(54) Title: COMPARTMENTALISED COMBINATORIAL CHEMISTRY BY MICROFLUIDIC CONTROL

(57) Abstract: The invention describes a method for the synthesis of compounds comprising the steps of: (a) compartmentalising two or more sets of primary compounds into microcapsules; such that a proportion of the microcapsules contains two or more compounds; and (b) forming secondary compounds in the microcapsules by chemical reactions between primary compounds from different sets; wherein one or both of steps (a) and (b) is performed under microfluidic control; preferably electronic microfluidic control. The invention further allows for the identification of compounds which bind to a target component of a biochemical system or modulate the activity of the target, and which is co-compartmentalised into the microcapsules.
COMPARTMENTALISED COMBINATORIAL CHEMISTRY BY
MICROFLUIDIC CONTROL

Related Applications

This application claims priority under 35 U.S.C. § 120, to PCT Application No. GB2004/001352 filed March 31, 2004, the entirety of which is incorporated herein by reference.

The present invention relates to methods for use in the synthesis and identification of molecules which bind to a target component of a biochemical system or modulate the activity of a target.

Over the past decade, high-throughput screening (HTS) of compound libraries has become a cornerstone technology of pharmaceutical research. Investment into HTS is substantial. A current estimate is that biological screening and preclinical pharmacological testing alone account for ~14% of the total research and development (R&D) expenditures of the pharmaceutical industry (Handen, Summer 2002). HTS has seen significant improvements in recent years, driven by a need to reduce operating costs and increase the number of compounds and targets that can be screened. Conventional 96-well plates have now largely been replaced by 384-well, 1536-well and even 3456-well formats. This, combined with commercially available plate-handling robotics allows the screening of 100,000 assays per day, or more, and significantly cuts costs per assay due to the miniaturisation of the assays.

HTS is complemented by several other developments. Combinatorial chemistry is a potent technology for creating large numbers of structurally related compounds for HTS. Currently, combinatorial synthesis mostly involves spatially resolved parallel synthesis. The number of compounds that can be synthesised is limited to hundreds or thousands but the compounds can be synthesised on a scale of milligrams or tens of milligrams, enabling full characterisation and even purification. Larger libraries can be synthesised using split synthesis on beads to generate one-bead-one compound libraries. This method
is much less widely adopted due to a series of limitations including: the need for solid phase synthesis; difficulties characterising the final products (due to the shear numbers and small scale); the small amounts of compound on a bead being only sufficient for one or a few assays; the difficulty in identifying the structure of a hit compound, which often relies on tagging or encoding methods and complicates both synthesis and analysis. Despite this split synthesis and single bead analysis still has promise. Recently there have been significant developments in miniaturised screening and single bead analysis. For example, printing techniques allow protein-binding assays to be performed on a slide containing 10,800 compound spots, each of 1 nl volume (Hergenrother et al., 2000).

CombiChem has so far, however, generated only a limited number of lead compounds. As of April 2000, only 10 compounds with a combinatorial chemistry history had entered clinical development and all but three of these are (oligo)nucleotides or peptides (Adang and Hermkens, 2001). Indeed, despite enormous investments in both HTS and combinatorial chemistry during the past decade the number of new drugs introduced per year has remained constant at best.

Dynamic combinatorial chemistry (DCC) can also be used to create dynamic combinatorial libraries (DCLs) from a set of reversibly interchanging components, however the sizes of libraries created and screened to date are still fairly limited (≤40,000) (Ramstrom and Lehn, 2002).

Virtual screening (VS) (Lyne, 2002), in which large compound bases are searched using computational approaches to identify a subset of candidate molecules for testing may also be very useful when integrated with HTS. However, there are to date few studies that directly compare the performance of VS and HTS, and further validation is required.

Microfluidic technology has been applied to high throughput screening methods. For example, US 6,508,988 describes combinatorial synthesis systems which rely on microfluidic flow to control the flow of reagents in a multichannel system. US 5,942,056, and continuations thereof, describes a microfluidic test system for performing high throughput screening assays, wherein test compounds can be flowed through a plurality of channels to perform multiple reactions contemporaneously.

Despite all these developments, current screening throughput is still far from adequate. Recent estimates of the number of individual genes in the human genome (~30,000) and
the number of unique chemical structures theoretically attainable using existing chemistries suggests that an enormous number of assays would be required to completely map the structure-activity space for all potential therapeutic targets (Burbach, 1998).

Hence, a method with the capability to both create and screen vast numbers ($\geq 10^{16}$) of compounds quickly, using reaction volumes of only a few femtolitres, and at very low cost should be of enormous utility in the generation of novel drug leads.

**SUMMARY OF THE INVENTION.**

The present inventors have found that the powerful technique of microfluidic control of microcapsules, in particular the electronic control of microfluid based technology can be applied to the compartmentalised microcapsule system described in Griffith & Tawfik (1998) which is herein incorporated by reference. The result is a novel method which is capable of creating and screening vast quantities of compounds both quickly and efficiently.

Thus, the invention, in a first aspect, provides a method for preparing a repertoire of compounds comprising the steps of:

(a) compartmentalising two or more sets of primary compounds into microcapsules; such that a proportion of the microcapsules contains multiple copies of one or more compounds representative of each of said sets, and wherein said one or more compounds represents a subset of the set of primary compounds; and

(b) forming secondary compounds in the microcapsules by chemical reactions between primary compounds from different sets; wherein either one or both of steps (a) and (b) is performed under the microfluidic control of fluidic species.

A compound is “representative” of a set where is is member of said set; advantageously, therefore, each microcapsule contains compound(s) from each set. Although a microcapsule may contain more than one different compound from each set, it contains only a proportion of said set — i.e. a subset. The subset of a set advantageously represents no more that 10% of the members of the set; preferably, this figure is 9%, 8%, 7%, 6%, 5%, 4%, 3%, 2%, 1% or less.
Most advantageously a microcapsule contains only a single compound from each set of primary compounds.

The sets of primary compounds used in the method of the invention can consist of any number of different compounds. At least a first set comprises two or more compounds; but the other set may be a single compound. Preferably, if a first set is a single compound, at least one further set comprises a repertoire of compounds. The larger this repertoire, the greater the number of different secondary compounds that will be generated.

Preferably, at least one set of compounds comprises a repertoire of different compounds. At least one set, however, may consist of a single compound, such that secondary compounds are all constructed based on or containing the single compound used in one set. The greater the number of sets, and the greater the diversity of each set, the greater the final diversity of the secondary compounds generated.

Advantageously, in step (a) the number of different compounds per compartment will be equivalent to the the number of primary compounds forming the secondary compound in step (b).

In a second aspect, the invention provides a method for identifying primary compounds which react together to form secondary compounds capable of binding to or modulating the activity of a target, comprising the steps of:

(a) compartmentalising two or more sets of primary compounds into microcapsules; such that a proportion of the microcapsules contains two or more compounds;

(b) forming secondary compounds in the microcapsules by chemical reactions between primary compounds from different sets; and

(c) identifying subsets of primary compounds which react to form secondary compounds which bind to or modulate the activity of the target; wherein one or more of steps (a), (b) and (c) is performed under the microfluidic control of fluidic species.

In a third aspect, the invention provides a method for synthesising compounds with enhanced ability to bind to or modulate the activity of the target, comprising the steps of:
(a) compartmentalising into microcapsules subsets of primary compounds identified in step (c) of the second aspect of the invention and, optionally, compartmentalising additional sets of primary compounds;

(b) forming secondary compounds in the microcapsules by chemical reactions between primary compounds from different sets; and

(c) identifying subsets of primary compounds which react to form secondary compounds which bind to or modulate the activity of the target; wherein one or more of steps (a), (b) and (c) is performed under the microfluidic control of fluidic species.

Advantageously, steps (a) to (c) can be repeated, but after the first cycle, step (a) comprises compartmentalising subsets of primary compounds identified in step (c) into microcapsules and, optionally, compartmentalising additional sets of compounds.

In a fourth aspect, the invention provides a method for identifying individual compounds which bind to or modulate the activity of the target, comprising the steps of:

(a) compartmentalising into microcapsules a primary compound identified in step (c) of the second or third aspect of the invention and additional sets of primary compounds;

(b) forming secondary compounds in the microcapsules by chemical reactions between primary compounds from different sets; and

(c) identifying subsets of primary compounds which react to form secondary compounds which bind to or modulate the activity of the target; wherein one or more of steps (a), (b) and (c) is performed under the microfluidic control of fluidic species.

If the secondary compound is formed by the chemical reaction between more than two primary compounds it can be identified by iteratively repeating steps (a) to (c), but after the first cycle, step (c) comprises compartmentalising the primary compound identified in step (c) of the second or third aspect of the invention, a primary compound identified in step (c) of each of the previous cycles (of the fourth aspect of the invention) and additional sets of primary molecules.
Preferably, the desired activity is selected from the group consisting of a binding activity and the modulation of the activity of a target. Advantageously, the target is compartmentalised into microcapsules together with the compounds.

Sets of compounds may be compartmentalised in different ways to achieve encapsulation of multiple copies of two or more compounds into microcapsules.

For example, small aliquots of an aqueous solution of each compound can be deposited into an oil phase (advantageously containing surfactants and/or other stabilising molecules) whilst applying mechanical energy, thereby dispersing each compound into multiple aqueous microcapsules, each of which contains (for the most part) a single sort of compound but multiple copies thereof. Advantageously, the compounds can be deposited into the oil phase in the form of droplets generated using inkjet printing technology (Calvert, 2001; de Gans et al., 2004), and more advantageously by piezoelectric drop-on-demand (DOD) inkjet printing technology. Inkjet printing technology can be used to mix primary compounds and, optionally, other reagents (e.g. the target and reagents to assay target activity) immediately prior to forming the emulsion. Advantageously, multiple compounds can be mixed with multiple targets in a combinatorial manner.

Thus, step (a) above can be modified such that it comprises forming separate emulsion compartments containing two or more compounds and mixing the emulsion compartments to form an emulsified compound repertoire wherein a subset of the repertoire is represented in multiple copies in any one microcapsule.

Moreover, compound libraries can be be compartmentalised in highly monodisperse microcapsules produced using microfluidic techniques. For example, aliquots of each compound can be compartmentalised into one or more aqueous microcapsules (with less than 1.5% polydispersity) in water-in-oil emulsions created by droplet break off in a coflowing stream of oil (Umbanhowar et al., 2000). Advantageously, the aqueous microcapsules are then transported by laminar-flow in a stream of oil in microfluidic channels (Thorsen et al., 2001). The microcapsules containing single compounds can, optionally, be split into two or more smaller microcapsules using microfluidics (Link et al., 2004; Song et al., 2003). Microcapsules containing primary compounds can be fused with other microcapsules (Song et al., 2003) to form secondary compounds.
Microcapsules containing compounds can also, optionally, be fused with microcapsules containing a target. A single microcapsule containing a target can, optionally, be split into two or more smaller microcapsules which can subsequently be fused with microcapsules containing different compounds, or compounds at different concentrations. Advantageously, a compound and a target can be mixed by microcapsule fusion prior to a second microcapsule fusion which delivers the reagents necessary to assay the activity of the target (e.g. the substrate for the target if the target is an enzyme). This allows time for the compound to bind to the target. The microcapsules can be analysed and, optionally, sorted using microfluidic devices (Fu et al., 2002).

In a further aspect, there is provided a method for preparing a repertoire of compounds comprising the steps of:

(a) attaching two or more sets of primary compounds onto microbeads;

(b) compartmentalising the microbeads into microcapsules such that a proportion of the microcapsules contains two or more microbeads;

(c) releasing at least one of the sets of primary compounds from the microbeads;

(d) forming secondary compounds in the microcapsules by chemical reactions between primary compounds from different sets; wherein one or more of steps (a), (b), (c) and (d) is performed under the microfluidic control of fluidic species.

Advantageously, the compounds are cleavable from the beads. Where more than two sets of compounds are used, all the sets with the exception of one are cleavable; preferably, they are all cleavable. The compounds may be attached to the microbeads by photochemically cleavable linkers.

In a still further aspect, the invention provides a method for identifying primary compounds which react together to form secondary compounds capable of binding to or modulating the activity of a target, comprising the steps of:

(a) attaching two or more sets of primary compounds onto microbeads;

(b) compartmentalising the microbeads into microcapsules together with the target such that many compartments contain two or more microbeads;
(c) releasing the primary compounds from the microbeads;

(d) forming secondary compounds in the microcapsules by chemical reactions between primary compounds from different sets; and

(e) identifying subsets of primary compounds which react to form secondary compounds which bind to or modulate the activity of the target; wherein one or more of steps (a), (b), (c), (d) and (e) is performed under the microfluidic control of fluidic species.

Advantageously, in step (b) the modal number of microbeads per compartment will be equivalent to the number of primary compounds forming the secondary compound in step (d).

In a further aspect, the invention provides a method for synthesising compounds with enhanced ability to bind to or modulate the activity of the target, comprising the steps of:

(a) attaching onto microbeads subsets of primary compounds identified in step (e) of the second aspect of the invention and, optionally, attaching additional sets of primary compounds;

(b) compartmentalising the microbeads into microcapsules together with the target such that many compartments contain two or more microbeads;

(c) releasing the primary compounds from the microbeads;

(d) forming secondary compounds in the microcapsules by chemical reactions between primary compounds from different sets; and

(e) identifying subsets of primary compounds which react to form secondary compounds which bind to or modulate the activity of the target; wherein one or more of steps (a), (b), (c), (d) and (e) is performed under the microfluidic control of fluidic species.

Advantageously, steps (a) to (e) can be repeated, but after the first cycle, step (a) comprises attaching onto microbeads subsets of primary compounds identified in step (e) and, optionally, attaching additional sets of compounds.
In a further aspect, the invention provides a method for identifying individual compounds which bind to or modulate the activity of the target, comprising the steps of:

(a) attaching onto microbeads a primary compound identified in step (e) of the second or third aspect of the invention and additional sets of primary compounds;

(b) compartmentalising the microbeads into microcapsules together with the target such that many compartments contain two or more microbeads;

(c) releasing the primary compounds from the microbeads;

(d) forming secondary compounds in the microcapsules by chemical reactions between primary compounds from different sets; and

(e) identifying subsets of primary compounds which react to form secondary compounds which bind to or modulate the activity of the target; wherein one or more of steps (a), (b), (c), (d) and (e) is performed under the microfluidic control of fluidic species.

If the secondary compound is formed by the chemical reaction between more than two primary compounds it can be identified by iteratively repeating steps (a) to (e), but after the first cycle, step (a) comprises attaching onto microbeads the primary compound identified in step (e) of the second or third aspect of the invention, a primary compound identified in step (e) of each of the previous cycles (of the fourth aspect of the invention) and additional sets of primary molecules.

Preferably, the desired activity is selected from the group consisting of a binding activity and the modulation of the activity of a target. Advantageously, the target is compartmentalised into microcapsules together with the microbeads.

According to a preferred implementation of the present invention, the compounds may be screened according to an activity of the compound or derivative thereof which makes the microcapsule detectable as a whole. Accordingly, the invention provides a method wherein a compound with the desired activity induces a change in the microcapsule, or a modification of one or more molecules within the microcapsule, which enables the microcapsule containing the compound and, optionally, the microbead carrying it to be identified. In this embodiment, therefore, the microcapsules are either: (a) physically
sorted from each other according to the activity of the compound(s) contained therein, by for example, placing an electric charge on the microcapsule and 'steering' the microcapsule using an electric field, and the contents of the sorted microcapsules analysed to determine the identity of the compound(s) which they contain; or (b) analysed directly without sorting to determine the identity of the compound(s) which the microcapsules contain.

According to a preferred embodiment of the present invention, the screening of compounds may be performed by, for example:

(I) In a first embodiment, the microcapsules are screened according to an activity of the compound or derivative thereof which makes the microcapsule detectable as a whole. Accordingly, the invention provides a method wherein a compound with the desired activity induces a change in the microcapsule, or a modification of one or more molecules within the microcapsule, which enables the microcapsule containing the compound and the microbead carrying it to be identified. In this embodiment, therefore, the microcapsules are either: (a) physically sorted from each other according to the activity of the compound(s) contained therein, the contents of the sorted microcapsules optionally pooled into one or more common compartments, and the microcapsule contents analysed to determine the identity of the compound(s); or (b) analysed directly without sorting to determine the identity of the compound(s) which the microcapsules contained. Where the microcapsule contains microbeads, the microbeads can be analysed to determine the compounds with which they are coated.

(II) In a second embodiment, microbeads are analysed following pooling of the microcapsules into one or more common compartments. In this embodiment, a compound having the desired activity modifies the microbead which carried it (and which resides in the same microcapsule) in such a way as to make it identifiable in a subsequent step. The reactions are stopped and the microcapsules are then broken so that all the contents of the individual microcapsules are pooled. Modified microbeads are identified and either: (a) physically sorted from each other according to the activity of the compound(s) coated on the microbeads, and the sorted microbeads analysed to determine the identity of the compound(s) with which they are/were coated; or (b) analysed directly without sorting to determine the identity of the compound(s) with which the microbeads
are/were coated. It is to be understood, of course, that modification of the microbead may be direct, in that it is caused by the direct action of the compound, or indirect, in which a series of reactions, one or more of which involve the compound having the desired activity, leads to modification of the microbead. Advantageously, the target is bound to the microbead and is a ligand and the compound within the microcapsule binds, directly or indirectly, to said ligand to enable the isolation of the microbead. In another configuration, a substrate for the target is and is bound to the microbead, and the activity of the compound within the microcapsule results, directly or indirectly, in the conversion of said substrate into a product which remains part of the microbead and enables its isolation. Alternatively, the activity of the compound may prevent or inhibit the conversion of said substrate into product. Moreover, the product of the activity of the compound within the microcapsule can result, directly or indirectly, in the generation of a product which is subsequently complexed with the microbead and enables its identification.

(III) In a third embodiment, the microbeads are analysed following pooling of the microcapsules into one or more common compartments. In this embodiment, a compound with a desired activity induces a change in the microcapsule containing the compound and the microbead which carries it. This change, when detected, triggers the modification of the microbead within the compartment. The reactions are stopped and the microcapsules are then broken so that all the contents of the individual microcapsules are pooled. Modified microbeads are identified and either: (a) physically sorted from each other according to the activity of the compound(s) coated on the microbeads, and the sorted microbeads analysed to determine the identity of the compound(s) with which they are/were coated; or (b) analysed directly without sorting to determine the identity of the compound(s) with which the microbeads are/were coated.

The microcapsules or microbeads may be modified by the action of the compound(s) such as to change their optical properties and/or electrical charge properties. For example, the modification of the microbead can enable it to be further modified outside the microcapsule so as to induce a change in its optical and/or electrical charge properties.
In another embodiment, the change in optical and/or electrical charge properties of the microcapsules or microbeads is due to binding of a compound with distinctive optical and/or electrical charge properties respectively to the target.

Moreover, the change in optical and/or electrical charge properties of the microcapsules or microbeads can be due to binding of a target with distinctive optical and/or electrical charge properties respectively by the compound.

The change in the optical and/or electrical charge properties of the microcapsule may be due to modulation of the activity of the target by the compound. The compound may activate or inhibit the activity of the target. For example, if the target is an enzyme, the substrate and the product of the reaction catalysed by the target can have different optical and/or electrical charge properties. Advantageously, the substrate and product have different fluorescence properties. In the case where the microcapsules contain microbeads, both the substrate and the product can have similar optical and/or electrical charge properties, but only the product of the reaction, and not the substrate, binds to, or reacts with, the microbead, thereby changing the optical and/or electrical charge properties of the microbead.

The change in optical and/or electrical charge properties of the microcapsules or microbeads can also be due to the different optical and/or electrical charge properties of the target and the product of the reaction being selected. Where both target and product have similar optical and/or electrical charge properties, only the product of the reaction being selected, and not the target, binds to, or reacts with, the microbead, thereby changing the optical and/or electrical charge properties of the microcapsules or microbeads.

In a further configuration, further reagents specifically bind to, or specifically react with, the product (and not the substrate) attached to or contained in the microcapsule or microbead, thereby altering the optical and/or electrical charge properties of the microcapsule or microbead.

Advantageously, microbeads modified directly or indirectly by the activity of the compound are further modified by Tyramide Signal Amplification (TSA™; NEN),
resulting directly or indirectly in a change in the optical properties of said microcapsules or microbeads thereby enabling their separation.

It is to be understood that the detected change in the compartment may be caused by the direct action of the compound, or indirect action, in which a series of reactions, one or more of which involve the compound having the desired activity leads to the detected change.

Where the compounds are attached to beads, the density with which compounds are coated onto the microbeads, combined with the size of the microcapsule will determine the concentration of the compound in the microcapsule. High compound coating densities and small microcapsules will both give higher compound concentrations which may be advantageous for the selection of molecules with a low affinity for the target. Conversely, low compound coating densities and large microcapsules will both give lower compound concentrations which may be advantageous for the selection of molecules with a high affinity for the target.

Preferably, microencapsulation is achieved by forming an emulsion.

The microbead can be nonmagnetic, magnetic or paramagnetic.

Repertoires of compounds can be encapsulated so as to have multiple copies of a single compound in a microcapsule in different ways. For example, thin tubes connected to the microfluidic device can be dipped into reservoirs containing the desired compounds, and capillary action can be used to draw the desired compound from the reservoir into the microfluidic device. This method allows the microfluidic device to be loaded with compounds prepared outside the device.

Moreover, compound libraries can be compartmentalised in highly monodisperse microcapsules produced using microfluidic techniques. For example, aliquots of each compound can be compartmentalised into one or more aqueous microcapsules (with less than 1.5% polydispersity) in water-in-oil emulsions created by droplet break off in a co-flowing steam of oil (Umbanhowar et al., 2000). Advantageously, the aqueous microcapsules are then transported by laminar-flow in a stream of oil in microfluidic
channels (Thorsen et al., 2001). These microcapsules containing single compounds can, optionally, be split into two or more smaller microcapsules using microfluidics (Link et al., 2004; Song et al., 2003). The microcapsules containing single compounds can, optionally be fused with other microcapsules (Song et al., 2003) containing a target. A single microcapsule containing a target can, optionally, be split into two or more smaller microcapsules which can subsequently be fused with microcapsules containing different compounds, or compounds at different concentrations. Advantageously, a compound and a target can be mixed by microcapsule fusion prior to a second microcapsule fusion which delivers the necessary to assay the activity of the target (e.g. the substrate for the target if the target is an enzyme). This allows time for the compound to bind to the target. The microcapsules can be analysed and, optionally, sorted using microfluidic devices (Fu et al., 2002).

In various aspects of the invention, a fluidic system as disclosed herein may include a droplet formation system, a droplet fusing system, a droplet splitting system, a sensing system, a controller, and/or a droplet sorting and/or separation system, or any combination of these systems. Such systems and methods may be positioned in any suitable order, depending on a particular application, and in some cases, multiple systems of a given type may be used, for example, two or more droplet formation systems, two or
more droplet separation systems, etc. As examples of arrangements, systems of the
invention can be arranged to form droplets, to dilute fluids, to control the concentration of
species within droplets, to sort droplets to select those with a desired concentration of
species or entities (e.g., droplets each containing one molecule of reactant), to fuse
individual droplets to cause reaction between species contained in the individual droplets,
to determine reaction(s) and/or rates of reaction(s) in one or more droplets, etc. Many
other arrangements can be practiced in accordance with the invention.

One aspect of the invention relates to systems and methods for producing droplets of a
first liquid surrounded by a second liquid. The first and second liquids may be
essentially immiscible in many cases, i.e., immiscible on a time scale of interest (e.g., the
time it takes a fluidic droplet to be transported through a particular system or device). In
certain cases, the droplets may each be substantially the same shape or size, as further
described below. The first liquid may also contain other species, for example, certain
molecular species (e.g., as further discussed below), cells, particles, etc.

In one set of embodiments, electric charge may be created on a first liquid surrounded by
a second liquid, which may cause the first liquid to separate into individual droplets
within the second liquid. In some embodiments, the first liquid and the second liquid
may be present in a channel, e.g., a microfluidic channel, or other constricted space that
facilitates application of an electric field to the first liquid (which may be “AC” or
alternating current, “DC” or direct current etc.), for example, by limiting movement of the
first liquid with respect to the second liquid. Thus, the first liquid can be present as a
series of individual charged and/or electrically inducible droplets within the second
liquid. In one embodiment, the electric force exerted on the fluidic droplet may be large
enough to cause the droplet to move within the second liquid. In some cases, the electric
force exerted on the fluidic droplet may be used to direct a desired motion of the droplet
within the second liquid, for example, to or within a channel or a microfluidic channel.

Electric charge may be created in the first liquid within the second liquid using any
suitable technique, for example, by placing the first liquid within an electric field (which
may be AC, DC, etc.), and/or causing a reaction to occur that causes the first liquid to
have an electric charge, for example, a chemical reaction, an ionic reaction, a

15
photocatalyzed reaction, etc. In one embodiment, the first liquid is an electrical conductor. As used herein, a "conductor" is a material having a conductivity of at least about the conductivity of 18 megohm (Mohm or MΩ) water. The second liquid surrounding the first liquid may have a conductivity less than that of the first liquid. For instance, the second liquid may be an insulator, relative to the first liquid, or at least a "leaky insulator," i.e., the second liquid is able to at least partially electrically insulate the first liquid for at least a short period of time. Those of ordinary skill in the art will be able to identify the conductivity of fluids. In one non-limiting embodiment, the first liquid may be substantially hydrophilic, and the second liquid surrounding the first liquid may be substantially hydrophobic. In an alternative embodiment, the microcapsules or microbeads are analysed by detection of a change in their fluorescence. For example, microbeads can be analysed by flow cytometry and, optionally sorted using a fluorescence activated cell sorter (FACS). The different fluorescence properties of the target and the product can be due to fluorescence resonance energy transfer (FRET).

In a further embodiment, the internal environment of the microcapsules can be modified by the addition of one or more reagents to the continuous phase of the emulsion. This allows reagents to be diffused in to the microcapsules during the reaction, if necessary.

The invention moreover relates to a method according to the preceding aspects, further comprising the step of isolating the secondary compound produced by reaction of the primary compounds and optionally further comprising the step of manufacturing one or more secondary compounds.

The invention also provides for a product when identified according to the invention. As used in this context, a "product" may refer to any compound, selectable according to the invention.

Further embodiments of the invention are described in the detailed description below and in the accompanying claims.

Figure 15. Compound screening using microdroplets in a microfluidic system. Panel A: schematic of the core system. Panel B: process block diagram showing the modules in the core system. Microdroplets containing a target enzyme are fused with microdroplets
each of which contain a different compound from a compound library. After allowing time for the compounds to bind to the target enzyme each microdroplet is fused with another microdroplet containing a fluorogenic enzyme substrate. The rate of the enzymatic reaction is determined by measuring the fluorescence of each microdroplet, ideally at multiple points (corresponding to different times). Microdroplets containing compounds with desired activities can, if required, be sorted and collected.

Figure 16. Examples of microdroplet formation and manipulation using microfluidics. Panel A: microdroplets can be created at up to $10^4$ sec$^{-1}$ by hydrodynamic-focussing (top two panels) and show <1.5% polydispersity (bottom panel). Panel B: microdroplets can be split symmetrically or asymmetrically. Panel C: microdroplets carrying positive (+q) and negative (−q) electrical charges fuse spontaneously. Panel D: charged microdroplets can also be steered using an applied electrical field (E).

Figure 17. Examples of PTP1B inhibitors. Compounds with a bis-difluoromethylene phosphonate moiety (e.g. 2) have significantly more potency than those with a single moiety (e.g. 1).

Figure 18. Screening PTP1B inhibitors using microencapsulation. Polystyrene beads with surface carboxylate groups, died with orange or red fluorochromes (Fulton et al., 1997), are derivatised with a phosphopeptide PTP1B substrate, and either PTP1B inhibitors or non-inhibitory compounds, attached via a cleavable linker (1). After mixing the beads, single beads and target enzyme (PTP1B) are colocalised in a microcompartment by forming a water-in-oil emulsion using a microfluidic device (2). The compound is released (photochemically) (3). Inhibitors reduce the amount of substrate converted to product (dephosphorylated peptide) (4). The enzyme reaction is stopped and the emulsion is broken (5). After labelling with green fluorescent anti-substrate antibodies, beads are analysed by 3-colour flow cytometry to simultaneously determine extent of inhibition and the compound on the beads (6). Compound libraries can be coupled to optically tagged beads (see below) and rapidly decoded by flow cytometry (at up to 100,000 beads s$^{-1}$). Hit compounds are re-synthesised for further characterisation (7) or elaborated and rescreened in a process of synthetic evolution (8).

Figure 19. Synthesising PTP1B inhibitors in an emulsion. Two types of beads are created, differentially labelled with orange and red fluorochromes, and derivatised with
two types of molecule, A or B (neither, one, or both of which contain a difluoromethylene phosphonate moiety), attached via a reversible connection (a Schiff base). Beads are emulsified using a microfluidic device to give, on average, two beads per compartment. The molecules, A & B, are released from the beads in the compartment and react to form a new molecule, A-B, (in solution). If A-B is a PTP1B inhibitor the PTP1B substrate also on the beads is not dephosphorylated and these beads identified by flow cytometry as Fig. 18.

**Figure 20. Small molecule evolution using four-component reactions.** Four sets of 25 beads are created, each derivatised with one of 25 variants of molecules A, B, C or D, emulsified to give, on average, 4 beads per compartment, the compounds released to synthesise a large combinatorial repertoire (4 x 10^5) in situ and screened as Fig. 18. Low affinity inhibitors will be ‘recombined’ by re-screening mixtures of beads carrying moieties identified in inhibitors. Beads carrying a moiety found in inhibitors (e.g. A_{10}) can also be mixed with complete sets of beads coated with B, C and D and screened. If a moiety (say B_4) is then identified as a component of an inhibitor, beads coated with A_{10} and B_3 can be mixed with complete sets of beads C and D and the process repeated. This process of ‘mutation’ also results in deconvolution. After fixing three of the four moieties in active compounds, deconvolution can be completed using multiplex bead analysis as above. Compounds can be re-diversified or ‘mutated’ using bead sets carrying variant, exploded sets of the molecules used in the original libraries.

**Figure 21. Compartmentalisation of small molecules in water-in-fluorocarbon emulsions.** Water-in-perfluorooctyl bromide emulsions were made containing texas red (1 mM) and calcein (1 mM) in the aqueous phase by homogenisation as described in example 6. The two emulsions were mixed by vortexing and imaged by epifluorescence microscopy after 24 hours. No exchange of texas-red (red fluorescence) and calcein (green fluorescence) between microdroplets could be observed.

**Figure 22. Primary compounds for the synthesis of PTP1B inhibitors.** An amine (A) and an aldehyde (B) with difluoromethylene phosphonate moieties. Amine A reacts with aldehyde B in the aqueous microcapsules of a water-in-oil emulsion to generate the imine C which is a potent PTP1B inhibitor. C can be reduced in situ using cyanoborohydride to generate the stable amine D.
Figure 23 Charged droplet generation. (A), Oil and water streams converge at a 30 micron orifice. A voltage $V$ applied to indium-tin-oxide (ITO) electrodes on the glass produces an electric field $E$ to capacitively charges the aqueous-oil interface. Drop size is independent of charge at low field strengths but decreases at higher fields, as shown in the photomicrographs, [(B) V=0, (C) V=400, (D) V=600 and (E) V=800] at higher fields. (F) Droplet size as a function of voltage showing the crossover between flow-dominated and field-dominated snap-off for three different flow rates of the continuous phase oil ($Q_c = 80$ nL/s, 110 nL/s, and 140 nL/s). The infusion rate of the water is constant $Q_w = 20$ nL/s.)

Figure 24 Coalescing drops. (A) Drops having opposite sign of electrostatic charge can be generated by applying a voltage across the two aqueous streams. (B) In the absence of the field the frequency and timing of drop formation at the two nozzles are independent and each nozzle produces a different size drop at a different frequency; infusion rates are the same at both nozzles. After the confluence of the two streams, drops from the upper and lower nozzles stay in their respective halves of the stream and due to surfactant there are no coalescence events even in the case of large slugs that fill the channel width. (C) With an applied voltage of 200V across the 500 micron separation of the nozzles, the drops simultaneously break-off from the two nozzles and are identical; simultaneous drop formation can be achieved for unequal infusion rates of the aqueous streams even up to a factor of two difference in volumes. (D) The fraction of the drops that encounter each other and coalesce increases linearly above a critical field when a surfactant, sorbitan-monooleate 3% is present.

Figure 25: Droplets carrying a pH sensitive dye coalesce with droplets of a different pH fluid. Chaotic advection rapidly mixes the two fluids through a combination of translation and rotation as the droplets pass around corners.

Figure 26: Diffusion limited and rapid mixing strategies. (A) Drops meet and coalesce along the direction of $E$ and then move off in a perpendicular direction, as sketched the counter rotating vortices after coalescence do not mix the two fluid parts as each vortex contains a single material. (B) As the drops approach each other the increasing field causes there interfaces to deform and (C) a bridge to jump out connecting the drops, to create (D) in the case of 20nm silica particles and MgCl$_2$ a sharp interface where the
particles begin to gel. (E) A typical unmixed droplet with particles in one hemisphere. (F) To achieve fast mixing, droplets are brought together in the direction perpendicular to the electric field and move off in the direction parallel to the direction they merged along. Counter rotating vortexes are then created where each vortex is composed of half of the contents from each of the premerger-droplets. (G) Shows a pH sensitive dye in the lower drop and a different pH fluid in the upper droplet. (H) After merger the droplets are split by a sharp line. (I) A uniform intensity indicating that mixing has been occurred is achieved in the droplet after it translates one diameter, typically this takes 1 to 2 ms.

**Figure 27** Time delay reaction module. (A) Droplets of perfluorodecaline alternate with aqueous droplets in a hexadecane carrier fluid. The ‘single-file’ ordering of the droplets provides for long delays with essentially no deviation in the precise spacing of aqueous droplets or droplet order. (B) Increasing the width and height of the channel to create a ‘large cross-sectional area’ channel provides for extremely long time delays from minutes to hours. The exact ordering and spacing between the droplets is not maintained in this type of delay line.

**Figure 28** Recharging neutral drops. (A) Schematic to recharge neutral drops by breaking them in the presence of an electric field. Uncharged drops \( q=0 \) are polarized in an electric field \( E_S \neq 0 \), and provided \( E_S \) is sufficiently large, as shown in the photomicrograph of (B), they break into two oppositely charged daughter drops in the extensional flow at a bifurcation. The enlargement of the dashed rectangle, shown in (C), reveals that the charged drops are stretched in the electric field \( E_S \) but return to spherical on contacting the electrodes indicated by dashed vertical lines.

**Figure 29** Detection module. One or more lasers are coupled to an optical fibre that is used to excite the fluorescence in each droplet as it passes over the fibre. The fluorescence is collected by the same fibre and dichroic beam splitters separate off specific wavelengths of the fluorescent light and the intensity of the fluorescence is measured with a photomultiplier tube (PMT) after the light passes through a band-pass filter.

**Figure 30** Manipulating charged drops. In (A) charged drops alternately enter the right and left channels when there is no field applied \( E_S=0 \). The sketch in (B) shows the layout for using an electric field \( E_S \) to select the channel charged drops will enter at a
bifurcation. When an electric field is applied to the right (C), the drops enter the right branch at the bifurcation; they enter the left branch when the field is reversed (D). After the bifurcation, the distance between drops is reduced to half what it was before indicating the oil stream is evenly divided. The inset of (D) shows the deformation in the shape of a highly charged drop in an electric field.

DETAILED DESCRIPTION OF THE INVENTION

Definitions

The term "microcapsule" is used herein in accordance with the meaning normally assigned thereto in the art and further described hereinbelow. In essence, however, a microcapsule is an artificial compartment whose delimiting borders restrict the exchange of the components of the molecular mechanisms described herein which allow the identification of the molecule with the desired activity. The delimiting borders preferably completely enclose the contents of the microcapsule. Preferably, the microcapsules used in the method of the present invention will be capable of being produced in very large numbers, and thereby to compartmentalise a library of compounds. Optionally, the compounds can be attached to microbeads. The microcapsules used herein allow mixing and sorting to be performed thereon, in order to facilitate the high throughput potential of the methods of the invention. Microcapsules according to the present invention can be a droplet of one fluid in a different fluid, where the confined components are soluble in the droplet but not in the carrier fluid, and in another embodiment there is another material defining a wall, such as a membrane (e.g. in the context of lipid vesicles; liposomes) or non-ionic surfactant vesicles, or those with rigid, nonpermeable membranes, or semipermeable membranes. Arrays of liquid droplets on solid surfaces, multiwell plates and "plugs" in microfluidic systems, that is fluid droplets that are not completely surrounded by a second fluid as defined herein, are not microcapsules as defined herein.

A “proportion” of the microcapsules, which is defined as comprising two or more compounds, or two or microbeads, is any fraction of the microcapsules in question, including all of said microcapsules. Advantageously, it is at least 25% thereof, preferably 50%, and more preferably 60%, 70%, 80%, 90% or 95%.
The term "microbead" is used herein in accordance with the meaning normally assigned thereto in the art and further described hereinbelow. Microbeads, are also known by those skilled in the art as microspheres, latex particles, beads, or minibeads, are available in diameters from 20 nm to 1 mm and can be made from a variety of materials including silica and a variety of polymers, copolymers and terpolymers. Highly uniform derivatised and non-derivatised nonmagnetic and paramagnetic microparticles (beads) are commercially available from many sources (e.g. Sigma, Bangs Laboratories, Luminex and Molecular Probes) (Fornusek and Vetvicka, 1986).

Microbeads can be "compartmentalised" in accordance with the present invention by distribution into microcapsules. For example, in a preferred aspect the microbeads can be placed in a water/oil mixture and emulsified to form a water-in-oil emulsion comprising microcapsules according to the invention. The concentration of the microbeads can be adjusted to control the number of microbeads, which on average, appear in each microcapsule. Advantageously, the concentration of the microbeads can be adjusted such that, on average a single microbead appears in only 10-20% of the microcapsules, thus assuring that there are very few microcapsules with more than one microbead.

The term "compound" is used herein in accordance with the meaning normally assigned thereto in the art. The term compound is used in its broadest sense i.e. a substance comprising two or more elements in fixed proportions, including molecules and supramolecular complexes. This definition includes small molecules (typically <500 Daltons) which make up the majority of pharmaceuticals. However, the definition also includes larger molecules, including polymers, for example polypeptides, nucleic acids and carbohydrates, and supramolecular complexes thereof.

The term "primary compound" is used herein to indicate a compound which is compartmentalised in a microcapsule or coupled to a bead.

The term "secondary compound" is used herein to indicate a compound which is formed by the reaction between two or more primary compounds in a microcapsule, optionally after the release of at least one of the primary molecules from a microbead. Advantageously, all primary molecules are released from the microbeads. The secondary compound may be the result of a covalent or non-covalent reaction between the primary compounds.
The term "scaffold" is used herein in accordance with the meaning normally assigned thereto in the art. That is to say a core portion of a molecule common to all members of a combinatorial library (Maclean et al., 1999). Secondary compounds may optionally comprise scaffolds.

A "repertoire" of compounds is a group of diverse compounds, which may also be referred to as a library of compounds. Repertoires of compounds may be generated by any means known in the art, including combinatorial chemistry, compound evolution, or purchased from commercial sources such as Sigma Aldrich, Discovery Partners International, Maybridge and Tripos. A repertoire advantageously comprises at least $10^3$, $10^4$, $10^5$, $10^6$, $10^7$, $10^8$, $10^9$, $10^{10}$, $10^{11}$ or more different compounds, which may be related or unrelated in structure or function.

A "set" of compounds may be a repertoire of compounds or any part of a repertoire, including a single compound species. The invention envisages the use of two or more sets of compounds, which are reacted together. The sets may be derived from a single repertoire, or a plurality of different repertoires.

Compounds can be "released" from a microbead by cleavage of a linker which effects the attachment of the compound to the microbead. Release of the compounds from the microbead allows the compounds to interact more freely with other contents of the microcapsule, and to be involved in reactions therein and optionally to become combined with other reagents to form new compounds, complexes, molecules or supramolecular complexes. Cleavage of linkers can be performed by any means, with means such as photochemical cleavage which can be effected from without the microcapsule being preferred. Photochemically cleavable linkers are known in the art (see for example (Gordon and Balasubramanian, 1999)) and further described below.

As used herein, the "target" is any compound, molecule, or supramolecular complex. Typical targets include targets of medical significance, including drug targets such as receptors, for example G protein coupled receptors and hormone receptors; transcription factors, protein kinases and phosphatases involved in signalling pathways; gene products specific to microorganisms, such as components of cell walls, replicases and other enzymes; industrially relevant targets, such as enzymes used in the food industry, reagents intended for research or production purposes, and the like.
An "activity", as referred to herein in connection with the modulation of an activity of a target, can be any activity of the target or an activity of a molecule which is influenced by the target, which is modulatable directly or indirectly by a compound or compounds as assayed herein. The activity of the target may be any measurable biological or chemical activity, including binding activity, an enzymatic activity, an activating or inhibitory activity on a third enzyme or other molecule, the ability to cause disease or influence metabolism or other functions, and the like. Activation and inhibition, as referred to herein, denote the increase or decrease of a desired activity 1.5 fold, 2 fold, 3 fold, 4 fold, 5 fold, 10 fold, 100 fold or more. Where the modulation is inactivation, the inactivation can be substantially complete inactivation. The desired activity may moreover be purely a binding activity, which may or may not involve the modulation of the activity of the target bound to.

A compound defined herein as "low molecular weight" or a "small molecule" is a molecule commonly referred to in the pharmaceutical arts as a "small molecule". Such compounds are smaller than polypeptides and other, large molecular complexes and can be easily administered to and assimilated by patients and other subjects. Small molecule drugs can advantageously be formulated for oral administration or intramuscular injection. For example, a small molecule may have a molecular weight of up to 2000 Dalton; preferably up to 1000 Dalton; advantageously between 250 and 750 Dalton; and more preferably less than 500 Dalton.

A "selectable change" is any change which can be measured and acted upon to identify or isolate the compound which causes it. The selection may take place at the level of the microcapsule, the microbead, or the compound itself, optionally when complexed with another reagent. A particularly advantageous embodiment is optical detection, in which the selectable change is a change in optical properties, which can be detected and acted upon for instance in a FACS device to separate microcapsules or microbeads displaying the desired change.

As used herein, a ‘change in optical properties’ refers to any change in absorption or emission of electromagnetic radiation, including changes in absorbance, luminescence, phosphorescence or fluorescence. All such properties are included in the term "optical". Microcapsules or microbeads can be identified and, optionally, sorted, for example, by
luminescence, fluorescence or phosphorescence activated sorting. In a preferred embodiment, flow cytometry is employed to identify and, optionally, sort microcapsules or microbeads. A variety of optical properties can be used for analysis and to trigger sorting, including light scattering (Kerker, 1983) and fluorescence polarisation (Rolland et al., 1985). In a highly preferred embodiment microcapsules or microbeads are analysed and, optionally, sorted using a fluorescence activated cell sorter (FACS) (Norman, 1980; Mackenzie and Pinder, 1986).

The compounds in microcapsules or on beads can be identified using a variety of techniques familiar to those skilled in the art, including mass spectroscopy, chemical tagging or optical tagging.

As used herein, “or” is understood to mean “inclusively or,” i.e., the inclusion of at least one, but including more than one, of a number or list of elements. In contrast, the term “exclusively or” refers to the inclusion of exactly one element of a number or list of elements.

The indefinite articles “a” and “an,” as used herein in the specification and in the claims, should be understood to mean “at least one.”

The term “about,” as used herein in reference to a numerical parameter (for example, a physical, chemical, electrical, or biological property), will be understood by those of ordinary skill in the art to be an approximation of a numerical value, the exact value of which may be subject to errors such as those resulting from measurement errors of the numerical parameter, uncertainties resulting from the variability and/or reproducibility of the numerical parameter (for example, in separate experiments), and the like.

As used herein, a “cell” is given its ordinary meaning as used in biology. The cell may be any cell or cell type. For example, the cell may be a bacterium or other single-cell organism, a plant cell, or an animal cell. If the cell is a single-cell organism, then the cell may be, for example, a protozoan, a trypanosome, an amoeba, a yeast cell, algae, etc. If the cell is an animal cell, the cell may be, for example, an invertebrate cell (e.g., a cell from a fruit fly), a fish cell (e.g., a zebrafish cell), an amphibian cell (e.g., a frog cell), a reptile cell, a bird cell, or a mammalian cell such as a primate cell, a bovine cell, a horse cell, a porcine cell, a goat cell, a dog cell, a cat cell, or a cell from a rodent such as a rat or
a mouse. If the cell is from a multicellular organism, the cell may be from any part of the organism. For instance, if the cell is from an animal, the cell may be a cardiac cell, a fibroblast, a keratinocyte, a heptacyte, a chondrocyte, a neural cell, a osteocyte, a muscle cell, a blood cell, an endothelial cell, an immune cell (e.g., a T-cell, a B-cell, a macrophage, a neutrophil, a basophil, a mast cell, an eosinophil), a stem cell, etc. In some cases, the cell may be a genetically engineered cell. In certain embodiments, the cell may be a Chinese hamster ovarian ("CHO") cell or a 3T3 cell.

"Microfluidic," as used herein, refers to a device, apparatus or system including at least one fluid channel having a cross-sectional dimension of less than 1 mm, and a ratio of length to largest cross-sectional dimension of at least 3:1. A "microfluidic channel," as used herein, is a channel meeting these criteria.

Accordingly the term 'microfluidic control' (of a system/method) as described herein refers to a method/system which comprises the use of device or apparatus including at least one fluid channel having a cross-sectional dimension of less than 1 mm, and a ratio of length to largest cross-sectional dimension of at least 3:1.

Electronic microfluidic control (of a method/system) as referred to herein refers to a microfluidic method/system in which one or more steps of the method/system involves the production of an electronic charge on at least a proportion of the microcapsules used in the microfluidic method/system.

[These definitions of micrfluidics etc are a little different between the two filings – should they be made consistent?]

The "cross-sectional dimension" of the channel is measured perpendicular to the direction of fluid flow. Most fluid channels in components of the invention have maximum cross-sectional dimensions less than 2 mm, and in some cases, less than 1 mm. In one set of embodiments, all fluid channels containing embodiments of the invention are microfluidic or have a largest cross sectional dimension of no more than 2 mm or 1 mm. In another embodiment, the fluid channels may be formed in part by a single component (e.g. an etched substrate or molded unit). Of course, larger channels, tubes, chambers, reservoirs, etc. can be used to store fluids in bulk and to deliver fluids to components of the invention. In one set of embodiments, the maximum cross-sectional dimension of the
channel(s) containing embodiments of the invention are less than 500 microns, less than 200 microns, less than 100 microns, less than 50 microns, or less than 25 microns.

A “channel,” as used herein, means a feature on or in an article (substrate) that at least partially directs the flow of a fluid. The channel can have any cross-sectional shape (circular, oval, triangular, irregular, square or rectangular, or the like) and can be covered or uncovered. In embodiments where it is completely covered, at least one portion of the channel can have a cross-section that is completely enclosed, or the entire channel may be completely enclosed along its entire length with the exception of its inlet(s) and outlet(s).

A channel may also have an aspect ratio (length to average cross sectional dimension) of at least 2:1, more typically at least 3:1, 5:1, or 10:1 or more. An open channel generally will include characteristics that facilitate control over fluid transport, e.g., structural characteristics (an elongated indentation) and/or physical or chemical characteristics (hydrophobicity vs. hydrophilicity) or other characteristics that can exert a force (e.g., a containing force) on a fluid. The fluid within the channel may partially or completely fill the channel. In some cases where an open channel is used, the fluid may be held within the channel, for example, using surface tension (i.e., a concave or convex meniscus).

The channel may be of any size, for example, having a largest dimension perpendicular to fluid flow of less than about 5 mm or 2 mm, or less than about 1 mm, or less than about 500 microns, less than about 200 microns, less than about 100 microns, less than about 60 microns, less than about 50 microns, less than about 40 microns, less than about 30 microns, less than about 25 microns, less than about 10 microns, less than about 3 microns, less than about 1 micron, less than about 300 nm, less than about 100 nm, less than about 30 nm, or less than about 10 nm. In some cases the dimensions of the channel may be chosen such that fluid is able to freely flow through the article or substrate. The dimensions of the channel may also be chosen, for example, to allow a certain volumetric or linear flowrate of fluid in the channel. Of course, the number of channels and the shape of the channels can be varied by any method known to those of ordinary skill in the art. In some cases, more than one channel or capillary may be used. For example, two or more channels may be used, where they are positioned inside each other, positioned adjacent to each other, positioned to intersect with each other, etc.
As used herein, "integral" means that portions of components are joined in such a way that they cannot be separated from each other without cutting or breaking the components from each other.

A "droplet," as used herein is an isolated portion of a first fluid that is completely surrounded by a second fluid. It is to be noted that a droplet is not necessarily spherical, but may assume other shapes as well, for example, depending on the external environment. In one embodiment, the droplet has a minimum cross-sectional dimension that is substantially equal to the largest dimension of the channel perpendicular to fluid flow in which the droplet is located.

The "average diameter" of a population of droplets is the arithmetic average of the diameters of the droplets. Those of ordinary skill in the art will be able to determine the average diameter of a population of droplets, for example, using laser light scattering or other known techniques. The diameter of a droplet, in a non-spherical droplet, is the mathematically-defined average diameter of the droplet, integrated across the entire surface. As non-limiting examples, the average diameter of a droplet may be less than about 1 mm, less than about 500 micrometers, less than about 200 micrometers, less than about 100 micrometers, less than about 75 micrometers, less than about 50 micrometers, less than about 25 micrometers, less than about 10 micrometers, or less than about 5 micrometers. The average diameter of the droplet may also be at least about 1 micrometer, at least about 2 micrometers, at least about 3 micrometers, at least about 5 micrometers, at least about 10 micrometers, at least about 15 micrometers, or at least about 20 micrometers in certain cases.

As used herein, a "fluid" is given its ordinary meaning, i.e., a liquid or a gas. Preferably a fluid is a liquid. The fluid may have any suitable viscosity that permits flow. If two or more fluids are present, each fluid may be independently selected among essentially any fluids (liquids, gases, and the like) by those of ordinary skill in the art, by considering the relationship between the fluids. The fluids may each be miscible or immiscible. For example, two fluids can be selected to be immiscible within the time frame of formation of a stream of fluids, or within the time frame of reaction or interaction. Where the portions remain liquid for a significant period of time then the fluids should be significantly immiscible. Where, after contact and/or formation, the dispersed portions
are quickly hardened by polymerization or the like, the fluids need not be as immiscible. Those of ordinary skill in the art can select suitable miscible or immiscible fluids, using contact angle measurements or the like, to carry out the techniques of the invention.

As used herein, a first entity is "surrounded" by a second entity if a closed loop can be drawn around the first entity through only the second entity. A first entity is "completely surrounded" if closed loops going through only the second entity can be drawn around the first entity regardless of direction. In one aspect, the first entity is a particle. In yet another aspect of the invention, the entities can both be fluids. For example, a hydrophilic liquid may be suspended in a hydrophobic liquid, a hydrophobic liquid may be suspended in a hydrophilic liquid, a gas bubble may be suspended in a liquid, etc. Typically, a hydrophobic liquid and a hydrophilic liquid are substantially immiscible with respect to each other, where the hydrophilic liquid has a greater affinity to water than does the hydrophobic liquid. Examples of hydrophilic liquids include, but are not limited to, water and other aqueous solutions comprising water, such as cell or biological media, ethanol, salt solutions, etc. Examples of hydrophobic liquids include, but are not limited to, oils such as hydrocarbons, silicon oils, fluorocarbon oils, organic solvents etc.

The term "determining," as used herein, generally refers to the analysis or measurement of a species, for example, quantitatively or qualitatively, or the detection of the presence or absence of the species. "Determining" may also refer to the analysis or measurement of an interaction between two or more species, for example, quantitatively or qualitatively, or by detecting the presence or absence of the interaction. Example techniques include, but are not limited to, spectroscopy such as infrared, absorption, fluorescence, UV/visible, FTIR ("Fourier Transform Infrared Spectroscopy"), or Raman; gravimetric techniques; ellipsometry; piezoelectric measurements; immunoassays; electrochemical measurements; optical measurements such as optical density measurements; circular dichroism; light scattering measurements such as quasielectric light scattering; polarimetry; refractometry; or turbidity measurements.

**General Techniques**

Unless defined otherwise, all technical and scientific terms used herein have the same meaning as commonly understood by one of ordinary skill in the art (e.g., in cell culture, molecular genetics, nucleic acid chemistry, hybridisation techniques and biochemistry).

(A) GENERAL DESCRIPTION

The microcapsules of the present invention require appropriate physical properties to allow the working of the invention.

First, to ensure that the compounds and the target may not diffuse between microcapsules, the contents of each microcapsule must be isolated from the contents of the surrounding microcapsules, so that there is no or little exchange of compounds and target between the microcapsules over the timescale of the experiment.

Second, the method of the present invention requires that there are only a limited number of beads per microcapsule. This ensures that the compounds and the target will be isolated from other beads.

Third, the formation and the composition of the microcapsules must not abolish the activity of the target.

Consequently, any microencapsulation system used must fulfil these three requirements. The appropriate system(s) may vary depending on the precise nature of the requirements in each application of the invention, as will be apparent to the skilled person.

A wide variety of microencapsulation procedures are available (see Benita, 1996) and may be used to create the microcapsules used in accordance with the present invention.

Indeed, more than 200 microencapsulation methods have been identified in the literature (Finch, 1993).

These include membrane enveloped aqueous vesicles such as lipid vesicles (liposomes) (New, 1990) and non-ionic surfactant vesicles (van Hal et al., 1996). These are closed-membranous capsules of single or multiple bilayers of non-covalently assembled
molecules, with each bilayer separated from its neighbour by an aqueous compartment. In the case of liposomes the membrane is composed of lipid molecules; these are usually phospholipids but sterols such as cholesterol may also be incorporated into the membranes (New, 1990). A variety of enzyme-catalysed biochemical reactions, including RNA and DNA polymerisation, can be performed within liposomes (Chakrabarti et al., 1994; Oberholzer et al., 1995a; Oberholzer et al., 1995b; Walde et al., 1994; Wick & Luisi, 1996).

With a membrane-enveloped vesicle system much of the aqueous phase is outside the vesicles and is therefore non-compartmentalised. This continuous, aqueous phase should be removed or the biological systems in it inhibited or destroyed in order that the reactions are limited to the microcapsules (Luisi et al., 1987).

Enzyme-catalysed biochemical reactions have also been demonstrated in microcapsules generated by a variety of other methods. Many enzymes are active in reverse micellar solutions (Bru & Walde, 1991; Bru & Walde, 1993; Creagh et al., 1993; Haber et al., 1993; Kumar et al., 1989; Luisi & B., 1987; Mao & Walde, 1991; Mao et al., 1992; Perez et al., 1992; Walde et al., 1994; Walde et al., 1993; Walde et al., 1988) such as the AOT-isooctane-water system (Menger & Yamada, 1979).

Microcapsules can also be generated by interfacial polymerisation and interfacial complexation (Whateley, 1996). Microcapsules of this sort can have rigid, nonpermeable membranes, or semipermeable membranes. Semipermeable microcapsules bordered by cellulose nitrate membranes, polyamide membranes and lipid-polyamide membranes can all support biochemical reactions, including multienzyme systems (Chang, 1987; Chang, 1992; Lim, 1984). Alginate/polylysine microcapsules (Lim & Sun, 1980), which can be formed under very mild conditions, have also proven to be very biocompatible, providing, for example, an effective method of encapsulating living cells and tissues (Chang, 1992; Sun et al., 1992).

Non-membranous microencapsulation systems based on phase partitioning of an aqueous environment in a colloidal system, such as an emulsion, may also be used.

 Preferably, the microcapsules of the present invention are formed from emulsions; heterogeneous systems of two immiscible liquid phases with one of the phases dispersed
in the other as droplets of microscopic or colloidal size (Becher, 1957; Sherman, 1968; Lissant, 1974; Lissant, 1984). Emulsions may be produced from any suitable combination of immiscible liquids. Preferably the emulsion of the present invention has water (containing the biochemical components) as the phase present in the form of finely divided droplets (the disperse, internal or discontinuous phase) and a hydrophobic, immiscible liquid (an oil') as the matrix in which these droplets are suspended (the nondisperse, continuous or external phase). Such emulsions are termed 'water-in-oil' (W/O). This has the advantage that the entire aqueous phase containing the biochemical components is compartmentalised in discreet droplets (the internal phase). The external phase, being a hydrophobic oil, generally contains none of the biochemical components and hence is inert.

The emulsion may be stabilised by addition of one or more surface-active agents (surfactants). These surfactants are termed emulsifying agents and act at the water/oil interface to prevent (or at least delay) separation of the phases. Many oils and many emulsifiers can be used for the generation of water-in-oil emulsions; a recent compilation listed over 16,000 surfactants, many of which are used as emulsifying agents (Ash and Ash, 1993). Suitable oils include light white mineral oil and decane. Suitable surfactants include: non-ionic surfactants (Schick, 1966) such as sorbitan monooleate (Span^®80; ICI), sorbitan monostearate (Span^®60; ICI), polyoxyethylene sorbitan monooleate (Tween^® 80; ICI), and octylphenoxethoxyethanol (Triton X-100); ionic surfactants such as sodium cholate and sodium taurocholate and sodium deoxycholate; chemically inert silicone-based surfactants such as polysiloxane-poly(ethyl-polyethylene glycol copolymer (Cetyl Dimethicone Copolyol) (e.g. Abil^®EM90; Goldschmidt); and cholesterol.

Emulsions with a fluorocarbon (or perfluorocarbon) continuous phase (Krafft et al., 2003; Riess, 2002) may be particularly advantageous. For example, stable water-in-perfluorooctyl bromide and water-in-perfluoroctylethane emulsions can be formed using F-alkyl dimorpholinophosphates as surfactants (Sadatler et al., 1996). Non-fluorinated compounds are essentially insoluble in fluorocarbons and perfluorocarbons (Curran, 1998; Hildebrand and Cochran, 1949; Hudlicky, 1992; Scott, 1948; Studer et al., 1997) and small drug-like molecules (typically <500 Da and Log P<5) (Lipinski et al., 2001) are
compartmentalised very effectively in the aqueous microcapsules of water-in-fluorocarbon and water-in-perfluorocarbon emulsions – with little or no exchange between microcapsules.

Advantageously, compounds can be compartmentalised in microcapsules comprising non-aqueous (organic) solvents. Non-fluorinated organic solvents are essentially insoluble and immiscible with fluorocarbons and perfluorocarbons (Curran, 1998; Hildebrand and Cochrane, 1949; Hudlisky, 1992; Scott, 1948; Studer et al., 1997) allowing the formation of emulsions with a fluorocarbon (or perfluorocarbon) continuous phase and a discontinuous phase formed from a non-aqueous solvent such as dichloromethane, chloroform, carbon tetrachloride, toluene, tetrahydrofuran, diethyl ether, and ethanol. The ability to form secondary compounds in microcapsules comprising non-aqueous solvents greatly expands the repertoire of chemical reactions that can be performed and secondary molecules that can be synthesised therein. Most of synthetic organic chemistry is carried out in organic solvents including dichloromethane, chloroform, carbon tetrachloride, toluene, tetrahydrofuran, diethyl ether, and ethanol. Organic molecules dissolve better in organic solvents. Electrostatic interactions are enhanced in organic solvents (due to the low dielectric constant), whereas they can be solvated and made less reactive in aqueous solvents. For example, much of contemporary organic chemistry involves reactions relating to carbonyl chemistry, including the use of metal enolates. Likewise for a growing number of other organometallic interactions. These reactions are often carried out under an inert atmosphere in anhydrous solvents (otherwise the reagents would be quenched by water). There are also a large number of reactions which use palladium catalysis including the Suzuki reaction and the Heck reaction.

Creation of an emulsion generally requires the application of mechanical energy to force the phases together. There are a variety of ways of doing this which utilise a variety of mechanical devices, including stirrers (such as magnetic stir-bars, propeller and turbine stirrers, paddle devices and whisks), homogenisers (including rotor-stator homogenisers, high-pressure valve homogenisers and jet homogenisers), colloid mills, ultrasound and 'membrane emulsification' devices (Becher, 1957; Dickinson, 1994).

Complicated biochemical processes, notably gene transcription and translation are also active in aqueous microcapsules formed in water-in-oil emulsions. This has enabled
compartmentalisation in water-in-oil emulsions to be used for the selection of genes, which are transcribed and translated in emulsion microcapsules and selected by the binding or catalytic activities of the proteins they encode (Doi and Yanagawa, 1999; Griffiths and Tawfik, 2003; Lee et al., 2002; Sepp et al., 2002; Tawfik and Griffiths, 1998). This was possible because the aqueous microcapsules formed in the emulsion were generally stable with little if any exchange of nucleic acids, proteins, or the products of enzyme catalysed reactions between microcapsules.

The technology exists to create emulsions with volumes all the way up to industrial scales of thousands of litres (Becher, 1957; Sherman, 1968; Lissant, 1974; Lissant, 1984).

The preferred microcapsule size will vary depending upon the precise requirements of any individual screening process that is to be performed according to the present invention. In all cases, there will be an optimal balance between the size of the compound library and the sensitivities of the assays to determine the identity of the compound and target activity.

The size of emulsion microcapsules may be varied simply by tailoring the emulsion conditions used to form the emulsion according to requirements of the screening system. The larger the microcapsule size, the larger is the volume that will be required to encapsulate a given compound library, since the ultimately limiting factor will be the size of the microcapsule and thus the number of microcapsules possible per unit volume.

Water-in-oil emulsions can be re-emulsified to create water-in-oil-in water double emulsions with an external (continuous) aqueous phase. These double emulsions can be analysed and, optionally, sorted using a flow cytometer (Bernath et al., 2004).

Highly monodisperse microcapsules can be produced using microfluidic techniques. For example, water-in-oil emulsions with less than 1.5% polydispersity can be generated by droplet break off in a co-flowing steam of oil (Umbanhowar et al., 2000). Microfluidic systems can also be used for laminar-flow of aqueous microdroplets dispersed in a stream of oil in microfluidic channels (Thorsen et al., 2001). This allows the construction of microfluidic devices for flow analysis and, optionally, flow sorting of microdroplets (Fu et al., 2002).
Advantageously, highly monodisperse microcapsules can be formed using systems and methods for the electronic control of fluidic species. [One aspect of the invention relates to systems and methods for producing droplets of fluid surrounded by a liquid. The fluid and the liquid may be essentially immiscible in many cases, i.e., immiscible on a time scale of interest (e.g., the time it takes a fluidic droplet to be transported through a particular system or device). In certain cases, the droplets may each be substantially the same shape or size, as further described below. The fluid may also contain other species, for example, certain molecular species (e.g., as further discussed below), cells, particles, etc.

In one set of embodiments, electric charge may be created on a fluid surrounded by a liquid, which may cause the fluid to separate into individual droplets within the liquid. In some embodiments, the fluid and the liquid may be present in a channel, e.g., a microfluidic channel, or other constricted space that facilitates application of an electric field to the fluid (which may be “AC” or alternating current, “DC” or direct current etc.), for example, by limiting movement of the fluid with respect to the liquid. Thus, the fluid can be present as a series of individual charged and/or electrically inducible droplets within the liquid. In one embodiment, the electric force exerted on the fluidic droplet may be large enough to cause the droplet to move within the liquid. In some cases, the electric force exerted on the fluidic droplet may be used to direct a desired motion of the droplet within the liquid, for example, to or within a channel or a microfluidic channel (e.g., as further described herein), etc. As one example, in apparatus 5 in Fig. 3A, droplets 15 created by fluid source 10 can be electrically charged using an electric field created by electric field generator 20.

Electric charge may be created in the fluid within the liquid using any suitable technique, for example, by placing the fluid within an electric field (which may be AC, DC, etc.), and/or causing a reaction to occur that causes the fluid to have an electric charge, for example, a chemical reaction, an ionic reaction, a photocatalyzed reaction, etc. In one embodiment, the fluid is an electrical conductor. As used herein, a “conductor” is a material having a conductivity of at least about the conductivity of 18 megohm (MOhm or Ω) water. The liquid surrounding the fluid may have a conductivity less than that of the fluid. For instance, the liquid may be an insulator, relative to the fluid, or at least a “leaky insulator,” i.e., the liquid is able to at least partially electrically insulate the fluid.
for at least a short period of time. Those of ordinary skill in the art will be able to identify
the conductivity of fluids. In one non-limiting embodiment, the fluid may be
substantially hydrophilic, and the liquid surrounding the fluid may be substantially
hydrophobic.

In some embodiments, the charge created on the fluid (for example, on a series of fluidic
droplets) may be at least about $10^{-22}$ C/micrometer$^3$. In certain cases, the charge may be
at least about $10^{-21}$ C/micrometer$^3$, and in other cases, the charge may be at least about $10^{-20}$
C/micrometer$^3$, at least about $10^{-19}$ C/micrometer$^3$, at least about $10^{-18}$ C/micrometer$^3$,
at least about $10^{-17}$ C/micrometer$^3$, at least about $10^{-16}$ C/micrometer$^3$, at least about $10^{-15}$
C/micrometer$^3$, at least about $10^{-14}$ C/micrometer$^3$, at least about $10^{-13}$ C/micrometer$^3$, at
least about $10^{-12}$ C/micrometer$^3$, at least about $10^{-11}$ C/micrometer$^3$, at least about $10^{-10}$
C/micrometer$^3$, or at least about $10^{-9}$ C/micrometer$^3$ or more. In certain embodiments, the
charge created on the fluid may be at least about $10^{-21}$ C/micrometer$^2$, and in some cases,
the charge may be at least about $10^{-20}$ C/micrometer$^2$, at least about $10^{-19}$ C/micrometer$^2$,
at least about $10^{-18}$ C/micrometer$^2$, at least about $10^{-17}$ C/micrometer$^2$, at least about $10^{-16}$
C/micrometer$^2$, at least about $10^{-15}$ C/micrometer$^2$, at least about $10^{-14}$ C/micrometer$^2$, or
at least about $10^{-13}$ C/micrometer$^2$ or more. In other embodiments, the charge may be at
least about $10^{-14}$ C/droplet, and, in some cases, at least about $10^{-13}$ C/droplet, in other
cases at least about $10^{-12}$ C/droplet, in other cases at least about $10^{-11}$ C/droplet, in other
cases at least about $10^{-10}$ C/droplet, or in still other cases at least about $10^{-9}$ C/droplet.

The electric field, in some embodiments, is generated from an electric field generator, i.e.,
a device or system able to create an electric field that can be applied to the fluid. The
electric field generator may produce an AC field (i.e., one that varies periodically with
respect to time, for example, sinusoidally, sawtooth, square, etc.), a DC field (i.e., one
that is constant with respect to time), a pulsed field, etc. The electric field generator may
be constructed and arranged to create an electric field within a fluid contained within a
channel or a microfluidic channel. The electric field generator may be integral to or
separate from the fluidic system containing the channel or microfluidic channel,
according to some embodiments. As used herein, “integral” means that portions of the
components integral to each other are joined in such a way that the components cannot be
manually separated from each other without cutting or breaking at least one of the
components.
Techniques for producing a suitable electric field (which may be AC, DC, etc.) are known to those of ordinary skill in the art. For example, in one embodiment, an electric field is produced by applying voltage across a pair of electrodes, which may be positioned on or embedded within the fluidic system (for example, within a substrate defining the channel or microfluidic channel), and/or positioned proximate the fluid such that at least a portion of the electric field interacts with the fluid. The electrodes can be fashioned from any suitable electrode material or materials known to those of ordinary skill in the art, including, but not limited to, silver, gold, copper, carbon, platinum, copper, tungsten, tin, cadmium, nickel, indium tin oxide ("ITO"), etc., as well as combinations thereof. In some cases, transparent or substantially transparent electrodes can be used. In certain embodiments, the electric field generator can be constructed and arranged (e.g., positioned) to create an electric field applicable to the fluid of at least about 0.01 V/micrometer, and, in some cases, at least about 0.03 V/micrometer, at least about 0.05 V/micrometer, at least about 0.08 V/micrometer, at least about 0.1 V/micrometer, at least about 0.3 V/micrometer, at least about 0.5 V/micrometer, at least about 0.7 V/micrometer, at least about 1 V/micrometer, at least about 1.2 V/micrometer, at least about 1.4 V/micrometer, at least about 1.6 V/micrometer, or at least about 2 V/micrometer. In some embodiments, even higher electric field intensities may be used, for example, at least about 2 V/micrometer, at least about 3 V/micrometer, at least about 5 V/micrometer, at least about 7 V/micrometer, or at least about 10 V/micrometer or more.

In some embodiments, an electric field may be applied to fluidic droplets to cause the droplets to experience an electric force. The electric force exerted on the fluidic droplets may be, in some cases, at least about $10^{-16}$ N/micrometer$^3$. In certain cases, the electric force exerted on the fluidic droplets may be greater, e.g., at least about $10^{-15}$ N/micrometer$^3$, at least about $10^{-14}$ N/micrometer$^3$, at least about $10^{-13}$ N/micrometer$^3$, at least about $10^{-12}$ N/micrometer$^3$, at least about $10^{-11}$ N/micrometer$^3$, at least about $10^{-10}$ N/micrometer$^3$, at least about $10^{-9}$ N/micrometer$^3$, at least about $10^{-8}$ N/micrometer$^3$, or at least about $10^{-7}$ N/micrometer$^3$ or more. In other embodiments, the electric force exerted on the fluidic droplets, relative to the surface area of the fluid, may be at least about $10^{-15}$ N/micrometer$^2$, and in some cases, at least about $10^{-14}$ N/micrometer$^2$, at least about $10^{-13}$ N/micrometer$^2$, at least about $10^{-12}$ N/micrometer$^2$, at least about $10^{-11}$ N/micrometer$^2$, at least about $10^{-10}$ N/micrometer$^2$, at least about $10^{-9}$ N/micrometer$^2$, at least about $10^{-8}$ N/micrometer$^2$, at least about $10^{-7}$ N/micrometer$^2$, or at least about $10^{-6}$ N/micrometer$^2$ or
more. In yet other embodiments, the electric force exerted on the fluidic droplets may be at least about 10^{-9} \text{ N}, at least about 10^{-8} \text{ N}, at least about 10^{-7} \text{ N}, at least about 10^{-6} \text{ N}, at least about 10^{-5} \text{ N}, or at least about 10^{-4} \text{ N} or more in some cases.

In some embodiments of the invention, systems and methods are provided for at least partially neutralizing an electric charge present on a fluidic droplet, for example, a fluidic droplet having an electric charge, as described above. For example, to at least partially neutralize the electric charge, the fluidic droplet may be passed through an electric field and/or brought near an electrode, e.g., using techniques such as those described herein. Upon exiting of the fluidic droplet from the electric field (i.e., such that the electric field no longer has a strength able to substantially affect the fluidic droplet), and/or other elimination of the electric field, the fluidic droplet may become electrically neutralized, and/or have a reduced electric charge.

In another set of embodiments, droplets of fluid can be created from a fluid surrounded by a liquid within a channel by altering the channel dimensions in a manner that is able to induce the fluid to form individual droplets. The channel may, for example, be a channel that expands relative to the direction of flow, e.g., such that the fluid does not adhere to the channel walls and forms individual droplets instead, or a channel that narrows relative to the direction of flow, e.g., such that the fluid is forced to coalesce into individual droplets. One example is shown in Fig. 7A, where channel 510 includes a flowing fluid 500 (flowing downwards), surrounded by liquid 505. Channel 510 narrows at location 501, causing fluid 500 to form a series of individual fluidic droplets 515. In other embodiments, internal obstructions may also be used to cause droplet formation to occur. For instance, baffles, ridges, posts, or the like may be used to disrupt liquid flow in a manner that causes the fluid to coalesce into fluidic droplets.

In some cases, the channel dimensions may be altered with respect to time (for example, mechanically or electromechanically, pneumatically, etc.) in such a manner as to cause the formation of individual fluidic droplets to occur. For example, the channel may be mechanically contracted ("squeezed") to cause droplet formation, or a fluid stream may be mechanically disrupted to cause droplet formation, for example, through the use of moving baffles, rotating blades, or the like. As a non-limiting example, in Fig. 7B, fluid 500 flows through channel 510 in a downward direction. Fluid 500 is surrounded by
liquid 505. Piezoelectric devices 520 positioned near or integral to channel 510 may then mechanically constrict or “squeeze” channel 510, causing fluid 500 to break up into individual fluidic droplets 515.

In yet another set of embodiments, individual fluidic droplets can be created and maintained in a system comprising three essentially mutually immiscible fluids (i.e., immiscible on a time scale of interest), where one fluid is a liquid carrier, and the second fluid and the third fluid alternate as individual fluidic droplets within the liquid carrier. In such a system, surfactants are not necessarily required to ensure separation of the fluidic droplets of the second and third fluids. As an example, with reference to Fig. 14A, within channel 700, a first fluid 701 and a second fluid 702 are each carried within liquid carrier 705. First fluid 701 and second fluid 702 alternate as a series of alternating, individual droplets, each carried by liquid carrier 705 within channel 700. As the first fluid, the second fluid, and the liquid carrier are all essentially mutually immiscible, any two of the fluids (or all three fluids) can come into contact without causing droplet coalescence to occur. A photomicrograph of an example of such a system is shown in Fig. 14B, illustrating first fluid 701 and second fluid 702, present as individual, alternating droplets, each contained within liquid carrier 705.

One example of a system involving three essentially mutually immiscible fluids is a silicone oil, a mineral oil, and an aqueous solution (i.e., water, or water containing one or more other species that are dissolved and/or suspended therein, for example, a salt solution, a saline solution, a suspension of water containing particles or cells, or the like). Another example of a system is a silicone oil, a fluorocarbon oil, and an aqueous solution. Yet another example of a system is a hydrocarbon oil (e.g., hexadecane), a fluorocarbon oil, and an aqueous solution. In these examples, any of these fluids may be used as the liquid carrier. Non-limiting examples of suitable fluorocarbon oils include octadecafluorodecahydronaphthalene:
or

1-(1,2,2,3,3,4,4,5,5,6,6-undecafluorocyclohexyl)ethanol:

A non-limiting example of such a system is illustrated in Fig. 14B. In this figure, fluidic network 710 includes a channel containing liquid carrier 705, and first fluid 701 and second fluid 702. Liquid carrier 705 is introduced into fluidic network 710 through inlet 725, while first fluid 701 is introduced through inlet 721, and second fluid 702 is introduced through inlet 722. Channel 716 within fluidic network 710 contains liquid carrier 715 introduced from inlet 725. Initially, first fluid 701 is introduced into liquid carrier 705, forming fluidic droplets therein. Next, second fluid 702 is introduced into liquid 705, forming fluidic droplets therein that are interspersed with the fluidic droplets containing first fluid 701. Thus, upon reaching channel 717, liquid carrier 705 contains a first set of fluidic droplets containing first fluid 701, interspersed with a second set of fluidic droplets containing second fluid 702. In the embodiment illustrated, channel 706 optionally comprises a series of bends, which may allow mixing to occur within each of the fluidic droplets, as further discussed below. However, it should be noted that in this embodiment, since first fluid 701 and second fluid 702 are essentially immiscible, significant fusion and/or mixing of the droplets containing first fluid 701 with the droplets containing second fluid 702 is not generally expected.

In some embodiments, the fluidic droplets may each be substantially the same shape and/or size. The shape and/or size can be determined, for example, by measuring the average diameter or other characteristic dimension of the droplets. The term
"determining," as used herein, generally refers to the analysis or measurement of a species, for example, quantitatively or qualitatively, and/or the detection of the presence or absence of the species. "Determining" may also refer to the analysis or measurement of an interaction between two or more species, for example, quantitatively or qualitatively, or by detecting the presence or absence of the interaction. Examples of suitable techniques include, but are not limited to, spectroscopy such as infrared, absorption, fluorescence, UV/visible, FTIR ("Fourier Transform Infrared Spectroscopy"), or Raman; gravimetric techniques; ellipsometry; piezoelectric measurements; immunoassays; electrochemical measurements; optical measurements such as optical density measurements; circular dichroism; light scattering measurements such as quasielectric light scattering; polarimetry; refractometry; or turbidity measurements.

The "average diameter" of a plurality or series of droplets is the arithmetic average of the average diameters of each of the droplets. Those of ordinary skill in the art will be able to determine the average diameter (or other characteristic dimension) of a plurality or series of droplets, for example, using laser light scattering, microscopic examination, or other known techniques. The diameter of a droplet, in a non-spherical droplet, is the mathematically-defined average diameter of the droplet, integrated across the entire surface. The average diameter of a droplet (and/or of a plurality or series of droplets) may be, for example, less than about 1 mm, less than about 500 micrometers, less than about 200 micrometers, less than about 100 micrometers, less than about 75 micrometers, less than about 50 micrometers, less than about 25 micrometers, less than about 10 micrometers, or less than about 5 micrometers in some cases. The average diameter may also be at least about 1 micrometer, at least about 2 micrometers, at least about 3 micrometers, at least about 5 micrometers, at least about 10 micrometers, at least about 15 micrometers, or at least about 20 micrometers in certain cases.

In certain instances, the invention provides for the production of droplets consisting essentially of a substantially uniform number of entities of a species therein (i.e., molecules, compounds, cells, particles, etc.). For example, about 90%, about 93%, about 95%, about 97%, about 98%, or about 99%, or more of a plurality or series of droplets may each contain the same number of entities of a particular species. For instance, a substantial number of fluidic droplets produced, e.g., as described above, may each contain 1 entity, 2 entities, 3 entities, 4 entities, 5 entities, 7 entities, 10 entities, 15
entities, 20 entities, 25 entities, 30 entities, 40 entities, 50 entities, 60 entities, 70 entities, 80 entities, 90 entities, 100 entities, etc., where the entities are molecules or macromolecules, cells, particles, etc. In some cases, the droplets may each independently contain a range of entities, for example, less than 20 entities, less than 15 entities, less than 10 entities, less than 7 entities, less than 5 entities, or less than 3 entities in some cases. In one set of embodiments, in a liquid containing droplets of fluid, some of which contain a species of interest and some of which do not contain the species of interest, the droplets of fluid may be screened or sorted for those droplets of fluid containing the species as further described below (e.g., using fluorescence or other techniques such as those described above), and in some cases, the droplets may be screened or sorted for those droplets of fluid containing a particular number or range of entities of the species of interest, e.g., as previously described. Thus, in some cases, a plurality or series of fluidic droplets, some of which contain the species and some of which do not, may be enriched (or depleted) in the ratio of droplets that do contain the species, for example, by a factor of at least about 2, at least about 3, at least about 5, at least about 10, at least about 15, at least about 20, at least about 50, at least about 100, at least about 125, at least about 150, at least about 200, at least about 250, at least about 500, at least about 750, at least about 1000, at least about 2000, or at least about 5000 or more in some cases. In other cases, the enrichment (or depletion) may be in a ratio of at least about 10^4, at least about 10^5, at least about 10^6, at least about 10^7, at least about 10^8, at least about 10^9, at least about 10^{10}, at least about 10^{11}, at least about 10^{12}, at least about 10^{13}, at least about 10^{14}, at least about 10^{15}, or more. For example, a fluidic droplet containing a particular species may be selected from a library of fluidic droplets containing various species, where the library may have about 10^5, about 10^6, about 10^7, about 10^8, about 10^9, about 10^{10}, about 10^{11}, about 10^{12}, about 10^{13}, about 10^{14}, about 10^{15}, or more items, for example, a DNA library, an RNA library, a protein library, a combinatorial chemistry library, etc. In certain embodiments, the droplets carrying the species may then be fused, reacted, or otherwise used or processed, etc., as further described below, for example, to initiate or determine a reaction.

The use of microfluidic handling to create microcapsules according to the invention has a number of advantages:

a) They allow the formation of highly monodisperse microcapsules (<1.5%
polydispersity), each of which functions as an almost identical, very small microreactor,

b) The microcapsules can have volumes ranging from about 1 femtolitre to about 1 nanolitre.

c) Compartmentalisation in microcapsules prevents diffusion and dispersion due to parabolic flow.

d) By using a perfluorocarbon carrier fluid it is possible to prevent exchange of molecules between microcapsules.

e) Compounds in microcapsules cannot react or interact with the fabric of the microchannels as they are separated by a layer of inert perfluorocarbon carrier fluid.

f) Microcapsules can be created at up to and including 10,000 s\(^{-1}\) and screened using optical methods at the same rate. This is a throughput of \(\sim 10^9\) per day.

Microcapsules can, advantageously, be fused or split. For example, aqueous microdroplets can be merged and split using microfluidics systems (Link et al., 2004; Song et al., 2003). Microcapsule fusion allows the mixing of reagents. Fusion, for example, of a microcapsule containing the target with a microcapsule containing the compound could initiate the reaction between target and compound. Microcapsule splitting allows single microcapsules to be split into two or more smaller microcapsules. For example a single microcapsule containing a compound can be split into multiple microcapsules which can then each be fused with a different microcapsule containing a different target. A single microcapsule containing a target can also be split into multiple microcapsules which can then each be fused with a different microcapsule containing a different compound, or compounds at different concentrations.

In one aspect, the invention relates to microfluidic systems and methods for splitting a fluidic droplet into two or more droplets. The fluidic droplet may be surrounded by a liquid, e.g., as previously described, and the fluid and the liquid are essentially immiscible in some cases. The two or more droplets created by splitting the original fluidic droplet may each be substantially the same shape and/or size, or the two or more droplets may have different shapes and/or sizes, depending on the conditions used to split the original
fluidic droplet. In many cases, the conditions used to split the original fluidic droplet can be controlled in some fashion, for example, manually or automatically (e.g., with a processor, as discussed below). In some cases, each droplet in a plurality or series of fluidic droplets may be independently controlled. For example, some droplets may be split into equal parts or unequal parts, while other droplets are not split.

According to one set of embodiments, a fluidic droplet can be split using an applied electric field. The electric field may be an AC field, a DC field, etc. The fluidic droplet, in this embodiment, may have a greater electrical conductivity than the surrounding liquid, and, in some cases, the fluidic droplet may be neutrally charged. In some embodiments, the droplets produced from the original fluidic droplet are of approximately equal shape and/or size. In certain embodiments, in an applied electric field, electric charge may be urged to migrate from the interior of the fluidic droplet to the surface to be distributed thereon, which may thereby cancel the electric field experienced in the interior of the droplet. In some embodiments, the electric charge on the surface of the fluidic droplet may also experience a force due to the applied electric field, which causes charges having opposite polarities to migrate in opposite directions. The charge migration may, in some cases, cause the drop to be pulled apart into two separate fluidic droplets. The electric field applied to the fluidic droplets may be created, for example, using the techniques described above, such as with a reaction an electric field generator, etc.

As a non-limiting example, in Fig. 1A, where no electric field is applied, fluidic droplets contained in channel 230 are carried by a surrounding liquid, which flows towards intersection 240, leading to channels 250 and 255. In this example, the surrounding liquid flows through channels 250 and 255 at equal flowrates. Thus, at intersection 240, fluidic droplets 215 do not have a preferred orientation or direction, and move into exit channels 250 and 255 with equal probability due to the surrounding liquid flow. In contrast, in Fig. 1B, while the surrounding liquid flows in the same fashion as Fig. 1A, under the influence of an applied electric field of 1.4 V/micrometers, fluidic droplets 215 are split into two droplets at intersection 240, forming new droplets 216 and 217. Droplet 216 moves to the left in channel 250, while droplet 217 moves to the right in channel 255.

A schematic of this process can be seen in Fig. 5, where a neutral fluidic droplet 530, surrounded by a liquid 535 in channel 540, is subjected to applied electric field 525,
created by electrodes 526 and 527. Electrode 526 is positioned near channel 542, while electrode 527 is positioned near channel 544. Under the influence of electric field 525, charge separation is induced within fluidic droplet 530, i.e., such that a positive charge is induced at one end of the droplet, while a negative charge is induced at the other end of the droplet. The droplet may then split into a negatively charged droplet 545 and a positively charged droplet 546, which then may travel in channels 542 and 544, respectively. In some cases, one or both of the electric charges on the resulting charged droplets may also be neutralized, as previously described.

The invention, in yet another aspect, relates to systems and methods for fusing or coalescing two or more fluidic droplets into one droplet. For example, in one set of embodiments, systems and methods are provided that are able to cause two or more droplets (e.g., arising from discontinuous streams of fluid) to fuse or coalesce into one droplet in cases where the two or more droplets ordinarily are unable to fuse or coalesce, for example, due to composition, surface tension, droplet size, the presence or absence of surfactants, etc. In certain microfluidic systems, the surface tension of the droplets, relative to the size of the droplets, may also prevent fusion or coalescence of the droplets from occurring in some cases.

In one embodiment, two fluidic droplets may be given opposite electric charges (i.e., positive and negative charges, not necessarily of the same magnitude), which may increase the electrical interaction of the two droplets such that fusion or coalescence of the droplets can occur due to their opposite electric charges, e.g., using the techniques described herein. For instance, an electric field may be applied to the droplets, the droplets may be passed through a capacitor, a chemical reaction may cause the droplets to become charged, etc. As an example, as is shown schematically in Fig. 13A, uncharged droplets 651 and 652, carried by a liquid 654 contained within a microfluidic channel
653, are brought into contact with each other, but the droplets are not able to fuse or coalesce, for instance, due to their size and/or surface tension. The droplets, in some cases, may not be able to fuse even if a surfactant is applied to lower the surface tension of the droplets. However, if the fluidic droplets are electrically charged with opposite charges (which can be, but are not necessarily of, the same magnitude), the droplets may be able to fuse or coalesce. For instance, in Fig. 13B, positively charged droplets 655 and negatively charged droplets 656 are directed generally towards each other such that the electrical interaction of the oppositely charged droplets causes the droplets to fuse into fused droplets 657.

In another embodiment, the fluidic droplets may not necessarily be given opposite electric charges (and, in some cases, may not be given any electric charge), and are fused through the use of dipoles induced in the fluidic droplets that causes the fluidic droplets to coalesce. In the example illustrated in Fig. 13C, droplets 660 and 661 (which may each independently be electrically charged or neutral), surrounded by liquid 665 in channel 670, move through the channel such that they are affected by an applied electric field 675. Electric field 675 may be an AC field, a DC field, etc., and may be created, for instance, using electrodes 676 and 677, as shown here. The induced dipoles in each of the fluidic droplets, as shown in Fig. 13C, may cause the fluidic droplets to become electrically attracted towards each other due to their local opposite charges, thus causing droplets 660 and 661 to fuse to produce droplet 663. In Fig. 13D, droplets 651 and 652 flow together to fuse to form droplet 653, which flows in a third channel.

It should be noted that, in various embodiments, the two or more droplets allowed to coalesce are not necessarily required to meet “head-on.” Any angle of contact, so long as at least some fusion of the droplets initially occurs, is sufficient. As an example, in Fig. 12H, droplets 73 and 74 each are traveling in substantially the same direction (e.g., at different velocities), and are able to meet and fuse. As another example, in Fig. 12I, droplets 73 and 74 meet at an angle and fuse. In Fig. 12J, three fluidic droplets 73, 74 and 68 meet and fuse to produce droplet 79.

Other examples of fusing or coalescing fluidic droplets are described in International Patent Application Serial No. PCT/US2004/010903, filed April 9, 2004 by Link, et al., incorporated herein by reference.
Fluidic handling of microcapsules therefore results in further advantages:

a) Microcapsules can be split into two or more smaller microdroplets allowing the reagents contained therein to be reacted with a series of different molecules in parallel or assayed in multiplicate.

b) Microcapsules can be fused. This allows molecules to be: (a) diluted, (b) mixed with other molecules, and (c) reactions initiated, terminated or modulated at precisely defined times.

c) Reagents can be mixed very rapidly (in <2 ms) in microcapsules using chaotic advection, allowing fast kinetic measurements and very high throughput.

d) Reagents can be mixed in a combinatorial manner. For example, allowing the effect of all possible pairwise combinations of compounds in a compound library on a target to be tested.

Creating and manipulated microcapsules in microfluidic systems means that:

a) Stable streams of microcapsules can be formed in microchannels and identified by their relative positions.

b) If the reactions are accompanied by an optical signal (e.g. a change in fluorescence) a spatially-resolved optical image of the microfluidic network allows time resolved measurements of the reactions in each microcapsules.

c) Microcapsules can be separated using a microfluidic flow sorter to allow recovery and further analysis or manipulation of the molecules they contain.

Screening/Sorting of microcapsules

In still another aspect, the invention provides systems and methods for screening or sorting fluidic droplets in a liquid, and in some cases, at relatively high rates. For example, a characteristic of a droplet may be sensed and/or determined in some fashion (e.g., as further described below), then the droplet may be directed towards a particular region of the device, for example, for sorting or screening purposes.
In some embodiments, a characteristic of a fluidic droplet may be sensed and/or determined in some fashion, for example, as described herein (e.g., fluorescence of the fluidic droplet may be determined), and, in response, an electric field may be applied or removed from the fluidic droplet to direct the fluidic droplet to a particular region (e.g. a channel). In some cases, high sorting speeds may be achievable using certain systems and methods of the invention. For instance, at least about 10 droplets per second may be determined and/or sorted in some cases, and in other cases, at least about 20 droplets per second, at least about 30 droplets per second, at least about 100 droplets per second, at least about 200 droplets per second, at least about 300 droplets per second, at least about 500 droplets per second, at least about 750 droplets per second, at least about 1000 droplets per second, at least about 1500 droplets per second, at least about 2000 droplets per second, at least about 3000 droplets per second, at least about 5000 droplets per second, at least about 7500 droplets per second, at least about 10,000 droplets per second, at least about 15,000 droplets per second, at least about 20,000 droplets per second, at least about 30,000 droplets per second, at least about 50,000 droplets per second, at least about 75,000 droplets per second, at least about 100,000 droplets per second, at least about 150,000 droplets per second, at least about 200,000 droplets per second, at least about 300,000 droplets per second, at least about 500,000 droplets per second, at least about 750,000 droplets per second, at least about 1,000,000 droplets per second, at least about 1,500,000 droplets per second, at least about 2,000,000 or more droplets per second, or at least about 3,000,000 or more droplets per second may be determined and/or sorted in such a fashion.

In one set of embodiments, a fluidic droplet may be directed by creating an electric charge (e.g., as previously described) on the droplet, and steering the droplet using an applied electric field, which may be an AC field, a DC field, etc. As an example, in reference to Figs. 2-4, an electric field may be selectively applied and removed (or a different electric field may be applied, e.g., a reversed electric field as shown in Fig. 4A) as needed to direct the fluidic droplet to a particular region. The electric field may be selectively applied and removed as needed, in some embodiments, without substantially altering the flow of the liquid containing the fluidic droplet. For example, a liquid may flow on a substantially steady-state basis (i.e., the average flowrate of the liquid containing the fluidic droplet deviates by less than 20% or less than 15% of the steady-state flow or the expected value of the flow of liquid with respect to time, and in some
cases, the average flowrate may deviate less than 10% or less than 5%) or other predetermined basis through a fluidic system of the invention (e.g., through a channel or a microchannel), and fluidic droplets contained within the liquid may be directed to various regions, e.g., using an electric field, without substantially altering the flow of the liquid through the fluidic system. As a particular example, in Figs. 2A, 3A and 4A, a liquid containing fluidic droplets 15 flows from fluid source 10, through channel 30 to intersection 40, and exits through channels 50 and 55. In Fig. 2A, fluidic droplets 15 are directed through both channels 50 and 55, while in Fig. 3A, fluidic droplets 15 are directed to only channel 55 and, in Fig. 4A, fluidic droplets 15 are directed to only channel 50.

In another set of embodiments, a fluidic droplet may be sorted or steered by inducing a dipole in the fluidic droplet (which may be initially charged or uncharged), and sorting or steering the droplet using an applied electric field. The electric field may be an AC field, a DC field, etc. For example, with reference to Fig. 9A, a channel 540, containing fluidic droplet 530 and liquid 535, divides into channel 542 and 544. Fluidic droplet 530 may have an electric charge, or it may be uncharged. Electrode 526 is positioned near channel 542, while electrode 527 is positioned near channel 544. Electrode 528 is positioned near the junction of channels 540, 542, and 544. In Figs. 9C and 9D, a dipole is induced in the fluidic droplet using electrodes 526, 527, and/or 528. In Fig. 9C, a dipole is induced in droplet 530 by applying an electric field 525 to the droplet using electrodes 527 and 528. Due to the strength of the electric field, the droplet is strongly attracted to the right, into channel 544. Similarly, in Fig. 9D, a dipole is induced in droplet 530 by applying an electric field 525 to the droplet using electrodes 526 and 528, causing the droplet to be attracted into channel 542. Thus, by applying the proper electric field, droplet 530 can be directed to either channel 542 or 544 as desired.

In other embodiments, however, the fluidic droplets may be screened or sorted within a fluidic system of the invention by altering the flow of the liquid containing the droplets. For instance, in one set of embodiments, a fluidic droplet may be steered or sorted by directing the liquid surrounding the fluidic droplet into a first channel, a second channel, etc. As a non-limiting example, with reference to Fig. 10A, fluidic droplet 570 is surrounded by a liquid 575 in channel 580. Channel 580 divides into three channels 581, 582, and 583. The flow of liquid 575 can be directed into any of channels 581, 582, and
583 as desired, for example, using flow-controlling devices known to those of ordinary 
skill in the art, for example, valves, pumps, pistons, etc. Thus, in Fig. 10B, fluidic droplet 
570 is directed into channel 581 by directing liquid 575 to flow into channel 581 
(indicated by arrows 574); in Fig. 10C, fluidic droplet 570 is directed into channel 582 by 
directing liquid 575 to flow into channel 582 (indicated by arrows 574); and in Fig. 10D, 
fluidic droplet 570 is directed into channel 583 by directing liquid 575 to flow into 
channel 583 (indicated by arrows 574).

However, it is preferred that control of the flow of liquids in microfluidic systems is not 
used to direct the flow of fluidic droplets therein, but that an alternative method is used. 
10 Advantageously, therefore, the microcapsules are not sorted by altering the direction of 
the flow of a carrier fluid in a microfluidic system.

In another set of embodiments, pressure within a fluidic system, for example, within 
different channels or within different portions of a channel, can be controlled to direct the 
flow of fluidic droplets. For example, a droplet can be directed toward a channel junction 
including multiple options for further direction of flow (e.g., directed toward a branch, or 
fork, in a channel defining optional downstream flow channels). Pressure within one or 
more of the optional downstream flow channels can be controlled to direct the droplet 
selectively into one of the channels, and changes in pressure can be effected on the order 
of the time required for successive droplets to reach the junction, such that the 
5 downstream flow path of each successive droplet can be independently controlled. In one 
arangement, the expansion and/or contraction of liquid reservoirs may be used to steer or 
sort a fluidic droplet into a channel, e.g., by causing directed movement of the liquid 
containing the fluidic droplet. The liquid reservoirs may be positioned such that, when 
activated, the movement of liquid caused by the activated reservoirs causes the liquid to 
flow in a preferred direction, carrying the fluidic droplet in that preferred direction. For 
instance, the expansion of a liquid reservoir may cause a flow of liquid towards the 
reservoir, while the contraction of a liquid reservoir may cause a flow of liquid away from 
the reservoir. In some cases, the expansion and/or contraction of the liquid reservoir may 
be combined with other flow-controlling devices and methods, e.g., as described herein. 
30 Non-limiting examples of devices able to cause the expansion and/or contraction of a 
liquid reservoir include pistons and piezoelectric components. In some cases,
piezoelectric components may be particularly useful due to their relatively rapid response times, e.g., in response to an electrical signal.

As a non-limiting example, in Fig. 11A, fluidic droplet 600 is surrounded by a liquid 605 in channel 610. Channel 610 divides into channels 611, 612. Positioned in fluidic communication with channels 611 and 612 are liquid reservoirs 617 and 618, which may be expanded and/or contracted, for instance, by piezoelectric components 615 and 616, by a piston (not shown), etc. In Fig. 11B, liquid reservoir 617 has been expanded, while liquid reservoir 618 has been contracted. The effect of the expansion/contractions of the reservoirs is to cause a net flow of liquid towards channel 611, as indicated by arrows 603. Thus, fluidic droplet 600, upon reaching the junction between the channels, is directed to channel 611 by the movement of liquid 605. The reverse situation is shown in Fig. 11C, where liquid reservoir 617 has contracted while liquid reservoir 618 has been expanded. A net flow of liquid occurs towards channel 612 (indicated by arrows 603), causing fluidic droplet 600 to move into channel 612. It should be noted, however, that reservoirs 617 and 618 do not both need to be activated to direct fluidic droplet 600 into channels 611 or 612. For example, in one embodiment, fluidic droplet 600 may be directed to channel 611 by the expansion of liquid reservoir 617 (without any alteration of reservoir 618), while in another embodiment, fluidic droplet 600 may be directed to channel 611 by the contraction of liquid reservoir 618 (without any alteration of reservoir 617). In some cases, more than two liquid reservoirs may be used.

In some embodiments, the fluidic droplets may be sorted into more than two channels. Non-limiting examples of embodiments of the invention having multiple regions within a fluidic system for the delivery of droplets are shown in Figs. 6A and 6B. Other arrangements are shown in Figs. 10A-10D. In Fig. 6A, charged droplets 315 in channel 330 may be directed as desired to any one of exit channels 350, 352, 354, or 356, by applying electric fields to control the movement of the droplets at intersections 340, 341, and 342, using electrodes 321/322, 323/324, and 325/326, respectively. In Fig. 6A, droplets 315 are directed to channel 354 using applied electric fields 300 and 301, using principles similar to those discussed above. Similarly, in Fig. 6B, charged droplets 415 in channel 430 can be directed to any one of exit channels 450, 452, 454, 456, or 458, by applying electric fields to control the movement of the droplets at intersections 440, 441, 442, and 443, using electrodes 421/422, 423/424, 425/426, and 427/428, respectively. In
In another example, in apparatus 5, as schematically illustrated in Fig. 2A, fluidic droplets 15 created by fluid source 10 are positively charged due to an applied electric field created using electric field generator 20, which comprises two electrodes 22, 24. Fluidic droplets 15 are directed through channel 30 by a liquid containing the droplets, and are directed towards intersection 40. At intersection 40, the fluidic droplets do not have a preferred orientation or direction, and move into exit channels 50 and 55 with equal probability (in this embodiment, liquid drains through both exit channels 50 and 55 at substantially equal rates). Similarly, fluidic droplets 115 created by fluid source 110 are negatively charged due to an applied electric field created using electric field generator 120, which comprises electrodes 122 and 124. After traveling through channel 130 towards intersection 140, the fluidic droplets do not have a preferred orientation or direction, and move into exit channels 150 and 155 with equal probability, as the liquid exits through exit channels 150 and 155 at substantially equal rates. A representative photomicrograph of intersection 140 is shown in Fig. 2B.

In the schematic diagram of Fig. 3A, an electric field 100 of 1.4 V/micrometer has been applied to apparatus 5 of Fig. 2A, in a direction towards the right of apparatus 5. Positively-charged fluidic droplets 15 in channel 30, upon reaching intersection 40, are directed to the right in channel 55 due to the applied electric field 100, while the liquid containing the droplets continues to exit through exit channels 50 and 55 at substantially equal rates. Similarly, negatively-charged fluidic droplets 115 in channel 130, upon reaching intersection 140, are directed to the left in channel 150 due to the applied electric field 100, while the liquid fluid continues to exit the device through exit channels 150 and 155 at substantially equal rates. Thus, electric field 100 can be used to direct fluidic droplets into particular channels as desired. A representative photomicrograph of intersection 140 is shown in Fig. 3B.

Fig. 4A is a schematic diagram of apparatus 5 of Fig. 2A, also with an applied electric field 100 of 1.4 V/micrometer, but in the opposite direction (i.e., -1.4 V/micrometer). In this figure, positively-charged fluidic droplets 15 in channel 30, upon reaching intersection 40, are directed to the left into channel 50 due to the applied electric field
100, while negatively-charged fluidic droplets 115 in channel 130, upon reaching 
intersection 140, are directed to the right into channel 155 due to applied electric field 
100. The liquid containing the droplets exits through exit channels 50 and 55, and 150 
and 155, at substantially equal rates. A representative photomicrograph of intersection 
140 is shown in Fig. 4B.

In some embodiments of the invention, a fluidic droplet may be sorted and/or split into 
two or more separate droplets, for example, depending on the particular application. Any 
of the above-described techniques may be used to split and/or sort droplets. As a non-
limiting example, by applying (or removing) a first electric field to a device (or a portion 
thereof), a fluidic droplet may be directed to a first region or channel; by applying (or 
removing) a second electric field to the device (or a portion thereof), the droplet may be 
directed to a second region or channel; by applying a third electric field to the device (or 
a portion thereof), the droplet may be directed to a third region or channel; etc., where 
the electric fields may differ in some way, for example, in intensity, direction, frequency, 
duration, etc. In a series of droplets, each droplet may be independently sorted and/or 
split; for example, some droplets may be directed to one location or another, while other 
droplets may be split into multiple droplets directed to two or more locations.

As one particular example, in Fig. 8A, fluidic droplet 550, surrounding liquid 555 in 
channel 560 may be directed to channel 556, channel 557, or be split in some fashion 
between channels 562 and 564. In Fig. 8B, by directing surrounding liquid 555 towards 
channel 562, fluidic droplet 550 may be directed towards the left into channel 562; in Fig. 
8C, by directing surrounding liquid 555 towards channel 564, fluidic droplet 550 may be 
directed towards the right into channel 564. In Fig. 8D, an electric field may be applied, 
in combination with control of the flow of liquid 555 surrounding fluidic droplet 550, that 
causes the droplet to impact junction 561, which may cause the droplet to split into two 
separate fluidic droplets 565, 566. Fluidic droplet 565 is directed to channel 562, while 
fluidic droplet 566 is directed to channel 566. A high degree of control of the applied 
electric field may be achieved to control droplet formation; thus, for example, after fluidic 
droplet 565 has been split into droplets 565 and 566, droplets 565 and 566 may be of 
substantially equal size, or either of droplets 565 and 566 may be larger, e.g., as is shown 
in Figs. 8E and 8F, respectively.
As another example, in Fig. 9A, channel 540, carrying fluidic droplet 530 and liquid 535, divides into channel 542 and 544. Fluidic droplet 530 may be electrically charged, or it may uncharged. Electrode 526 is positioned near channel 542, while electrode 527 is positioned near channel 544. Electrode 528 is positioned near the junction of channels 540, 542, and 544. When fluidic droplet 530 reaches the junction, it may be subjected to an electric field, and/or directed to a channel or other region, for example, by directing the surrounding liquid into the channel. As shown in Fig. 9B, fluidic droplet 530 may be split into two separate droplets 565 and 566 by applying an electric field 525 to the droplet using electrodes 526 and 527. In Fig. 9C, a dipole can be induced in droplet 530 by applying an electric field 525 to the droplet using electrodes 527 and 528. Due to the strength of the applied electric field, the droplet may be strongly attracted to the right, into channel 544. Similarly, in Fig. 9D, a dipole may be induced in droplet 530 by applying an electric field 525 to the droplet using electrodes 526 and 528, causing the droplet to be attracted into channel 542. By controlling which electrodes are used to induce an electric field across droplet 530, and/or the strength of the applied electric field, one or more fluidic droplets within channel 540 may be sorted and/or split into two droplets, and each droplet may independently be sorted and/or split.

For example, highly monodisperse microcapsules containing a target enzyme can be fused with highly monodisperse microcapsules each of which contain a different compound from a compound library. The fused microcapsules flow along a microfluidic channel, allowing time for the compounds to bind to the target enzyme. Each microcapsule is then fused with another microdroplet containing, for example, a fluorogenic enzyme substrate. The rate of the enzymatic reaction is determined by measuring the fluorescence of each microdroplet, ideally at multiple points (corresponding to different times).

Microcapsules can be optically tagged by, for example, incorporating fluorochromes. In a preferred configuration, the microcapsules are optically tagged by incorporating quantum dots: quantum dots of 6 colours at 10 concentrations would allow the encoding of $10^6$ microcapsules (Han et al., 2001). Microcapsules flowing in an ordered sequence in a microfluidic channel can be encoded (wholly or partially) by their sequence in the stream of microcapsules (positional encoding).
Microbeads, also known by those skilled in the art as microspheres, latex particles, beads, or minibeads, are available in diameters from 20 nm to 1 mm and can be made from a variety of materials including silica and a variety of polymers, copolymers and terpolymers including polystyrene (PS), polymethylmethacrylate (PMMA), polyvinyltoluene (PVT), styrene/butadiene (S/B) copolymer, and styrene/vinyltoluene (S/VT) copolymer (www.bangslabs.com). They are available with a variety of surface chemistries from hydrophobic surfaces (e.g. plain polystyrene), to very hydrophilic surfaces imparted by a wide variety of functional surface groups: aldehyde, aliphatic amine, amide, aromatic amine, carboxylic acid, chloromethyl, epoxy, hydrazide, hydroxyl, sulfonate and tosyl. The functional groups permit a wide range of covalent coupling reactions for stable or reversible attachment of compounds to the microbead surface.

Microbeads can be optically tagged by, for example, incorporating fluorochromes. For example, one hundred different bead sets have been created, each with a unique spectral address due to labelling with precise ratios of red (>650 nm) and orange (585 nm) fluorochromes (Fulton et al., 1997) (www.luminex.com) and sets of up to $10^6$ beads can be encoded by incorporating quantum dots of 10 intensities and 6 colours (Han et al., 2001).

The compounds can be connected to the microbeads either covalently or non-covalently by a variety of means that will be familiar to those skilled in the art (see, for example, (Hermanson, 1996)). Advantageously, the compounds are attached via a cleavable linker. A variety of such linkers are familiar to those skilled in the art (see for example, Gordon and Balasubramanian, 1999)), including for example, linkers which can be cleaved photochemically and reversible covalent bonds which can be controlled by changing the pH (e.g. imines and acylhydrazones), by adjusting the oxido-reductive properties (e.g. disulphides), or using an external catalyst (e.g. cross-metathesis and transamidation).

The method of the present invention permits the identification of compounds which modulate the activity of the target in a desired way in pools (libraries or repertoires) of compounds.

In a highly preferred application, the method of the present invention is useful for screening libraries of compounds. The invention accordingly provides a method
according to preceding aspects of the invention, wherein the compounds are identified from a library of compounds.

The compounds identified according to the invention are advantageously of pharmacological or industrial interest, including activators or inhibitors of biological systems, such as cellular signal transduction mechanisms suitable for diagnostic and therapeutic applications. In addition the compounds identified according to the invention may be non-biological in nature. In a preferred aspect, therefore, the invention permits the identification of clinically or industrially useful products. In a further aspect of the invention, there is provided a product when isolated by the method of the invention.

The selection of suitable encapsulation conditions is desirable. Depending on the complexity and size of the compound library to be screened, it may be beneficial to set up the encapsulation procedure such that one or less than one secondary compound is formed per microcapsule. This will provide the greatest power of resolution. Where the library is larger and/or more complex, however, this may be impracticable; it may be preferable to form several secondary compounds together and rely on repeated application of the method of the invention to identify the desired compound. A combination of encapsulation procedures may be used to identify the desired compound.

Theoretical studies indicate that the larger the number of compounds created the more likely it is that a compound will be created with the properties desired (see (Perelson and Oster, 1979) for a description of how this applies to repertoires of antibodies). It has also been confirmed practically that larger phage-antibody repertoires do indeed give rise to more antibodies with better binding affinities than smaller repertoires (Griffiths et al., 1994). To ensure that rare variants are generated and thus are capable of being identified, a large library size is desirable. Thus, the use of optimally small microcapsules is beneficial.

The largest repertoires of compounds that can be screened in a single experiment to date, using two dimensional microarrays of 1 nl volume spots, is ~10^3 (Hergenrother et al., 2000). Using the present invention, at a microcapsule diameter of 2.6 mm (Tawfik and Griffiths, 1998), by forming a three-dimensional dispersion, a repertoire size of at least 10^{11} can be screened using 1ml aqueous phase in a 20 ml emulsion.
In addition to the compounds, or microbeads coated with compounds, described above, the microcapsules according to the invention will comprise further components required for the screening process to take place. They will comprise the target and a suitable buffer. A suitable buffer will be one in which all of the desired components of the biological system are active and will therefore depend upon the requirements of each specific reaction system. Buffers suitable for biological and/or chemical reactions are known in the art and recipes provided in various laboratory texts, such as (Sambrook and Russell, 2001).

Other components of the system will comprise those necessary for assaying the activity of the target. These may for example comprise substrate(s) and cofactor(s) for a reaction catalysed by the target, and ligand(s) bound by the target. They may also comprise other catalysts (including enzymes), substrates and cofactors for reactions coupled to the activity of the target which allow for the activity of the target to be detected.

(B) SCREENING PROCEDURES

To screen compounds which bind to or modulate the activity of a target, the target is compartmentalised in microcapsules together with one or more compounds or compound-coated microbeads. Advantageously each microcapsule contains only a single sort of secondary compound, but many copies thereof. Advantageously each microbead is coated with only a single sort of compound, but many copies thereof. Advantageously the compounds are connected to the microbeads via a cleavable linker, allowing them to be released from the microbeads in the compartments. Advantageously, each microcapsule or microbead is optically tagged to allow identification of the compounds contained within the microcapsule of attached to the microbead.

(i) SCREENING FOR BINDING

Compounds can be screened directly for binding to a target. In this embodiment, if the compound is attached to a microbead and has affinity for the target it will be bound by the target. At the end of the reaction, all of the microcapsules are combined, and all microbeads pooled together in one environment. Microbeads carrying compounds exhibiting the desired binding can be selected by affinity purification using a molecule that specifically binds to, or reacts specifically with, the target.
In an alternative embodiment, the target can be attached to microbeads by a variety of means familiar to those skilled in the art (see for example (Hermanson, 1996)). The compounds to be screened contain a common feature - a tag. The compounds are released from the microbeads and if the compound has affinity for the target, it will bind to it. At the end of the reaction, all of the microcapsules are combined, and all microbeads pooled together in one environment. Microbeads carrying compounds exhibiting the desired binding can be selected by affinity purification using a molecule that specifically binds to, or reacts specifically with, the "tag".

In an alternative embodiment, microbeads may be screened on the basis that the compound, which binds to the target, merely hides the ligand from, for example, further binding partners. In this eventuality, the microbead, rather than being retained during an affinity purification step, may be selectively eluted whilst other microbeads are bound.

Sorting by affinity is dependent on the presence of two members of a binding pair in such conditions that binding may occur. Any binding pair may be used for this purpose. As used herein, the term binding pair refers to any pair of molecules capable of binding to one another. Examples of binding pairs that may be used in the present invention include an antigen and an antibody or fragment thereof capable of binding the antigen, the biotin-avidin/streptavidin pair (Savage et al., 1994), a calcium-dependent binding polypeptide and ligand thereof (e.g. calmodulin and a calmodulin-binding peptide (Montigiani et al., 1996; Stofko et al., 1992), pairs of polypeptides which assemble to form a leucine zipper (Tripet et al., 1996), histidines (typically hexahistidine peptides) and chelated Cu\(^{2+}\), Zn\(^{2+}\) and Ni\(^{2+}\), (e.g. Ni-NTA; (Hochuli et al., 1987)), RNA-binding and DNA-binding proteins (Klug, 1995) including those containing zinc-finger motifs (Klug and Schwabe, 1995) and DNA methyltransferases (Anderson, 1993), and their nucleic acid binding sites.

In an alternative embodiment, compounds can be screened for binding to a target using a change in the optical properties of the microcapsule or the microbead.

The change in optical properties of the microcapsule or the microbead after binding of the compound to the target may be induced in a variety of ways, including:

(1) the compound itself may have distinctive optical properties, for example, it is fluorescent
(2) the optical properties of the compound may be modified on binding to the target, for example, the fluorescence of the compound is quenched or enhanced on binding (Voss, 1993; Masui and Kuramitsu, 1998).

(3) the optical properties of the target may be modified on binding of the compound, for example, the fluorescence of the target is quenched or enhanced on binding (Guixe et al., 1998; Qi and Grabowski, 1998)

(4) the optical properties of both target and compound are modified on binding, for example, there can be a fluorescence resonance energy transfer (FRET) from target to compound (or vice versa) resulting in emission at the "acceptor" emission wavelength when excitation is at the "donor" absorption wavelength (Heim & Tsien, 1996; Mahajan et al., 1998; Miyawaki et al., 1997).

The invention provides a method wherein a compound with the desired activity induces a change in the optical properties of the microcapsule, which enables the microcapsule containing the compound and the microbeads contained therein to be identified, and optionally, sorted.

In an alternative embodiment, the invention provides a method wherein microbeads are analysed following pooling of the microcapsules into one or more common compartments. In this embodiment, a compound having the desired activity modifies the optical properties of the microbead which carried it (and which resides in the same microcapsule) to allow it to be identified, and optionally, sorted.

In this embodiment, it is not necessary for binding of the compound to the target to directly induce a change in optical properties.

In this embodiment, if the compound attached to the microbead has affinity for the target it will be bound by the target. At the end of the reaction, all of the microcapsules are combined, and all microbeads pooled together in one environment. Microbeads carrying compounds exhibiting the desired binding can be identified by adding reagents that specifically bind to, or react specifically with, the target and thereby induce a change in the optical properties of the microbeads allowing their identification. For example, a fluorescently-labelled anti-target antibody can be used, or an anti-target antibody followed by a second fluorescently labelled antibody which binds the first.
In an alternative embodiment, the target can be attached to the microbeads by a variety of means familiar to those skilled in the art (see for example (Hermanson, 1996)). The compounds to be screened contain a common feature - a tag. The compounds are released from the microbeads and if the compound has affinity for the target, it will bind to it. At the end of the reaction, all of the microcapsules are combined, and all microbeads pooled together in one environment. Microbeads carrying compounds exhibiting the desired binding can be identified by adding reagents that specifically bind to, or react specifically with, the “tag” and thereby induce a change in the optical properties of the microbeads allowing their identification. For example, a fluorescently-labelled anti-“tag” antibody can be used, or an anti-“tag” antibody followed by a second fluorescently labelled antibody which binds the first.

In an alternative embodiment, microbeads may be identified on the basis that the gene product, which binds to the ligand, merely hides the ligand from, for example, further binding partners which would otherwise modify the optical properties of the microbeads. In this case microbeads with unmodified optical properties would be selected.

Fluorescence may be enhanced by the use of Tyramide Signal Amplification (TSA\textsuperscript{TM}) amplification to make the microbeads fluorescent (Sepp et al., 2002). This involves peroxidase (linked to another compound) binding to the microbeads and catalysing the conversion of fluorescein-tyramine in to a free radical form which then reacts (locally) with the microbeads. Methods for performing TSA are known in the art, and kits are available commercially from NEN.

TSA may be configured such that it results in a direct increase in the fluorescence of the microbeads, or such that a ligand is attached to the microbeads which is bound by a second fluorescent molecule, or a sequence of molecules, one or more of which is fluorescent.

(ii) SCREENING FOR REGULATION OF BINDING

In an alternative embodiment, the invention can be used to screen compounds which act to regulate a biochemical process. If the compound activates a binding activity of a target, a ligand for the target which is activated can be attached to microbeads by a variety of means familiar to those skilled in the art (see for example (Hermanson, 1996)). At the end
of the reaction, all of the microcapsules are combined, and all microbeads pooled together in one environment. Microbeads carrying compounds exhibiting the desired binding can be selected by affinity purification using a molecule that specifically binds to, or reacts specifically with, the target.

In an alternative embodiment, microbeads may be screened on the basis that the compound inhibits the binding activity of a target. In this eventuality, the microbead, rather than being retained during an affinity purification step, may be selectively eluted whilst other microbeads are bound.

In an alternative embodiment, compounds can be screened for the ability to modulates a binding activity of a target using a change in the optical properties of the microcapsule or the microbead.

The change in optical properties of the microcapsule or the microbead after binding of the target to its ligand may be induced in a variety of ways, including:

(1) the ligand itself may have distinctive optical properties, for example, it is fluorescent

(2) the optical properties of the ligand may be modified on binding to the target, for example, the fluorescence of the ligand is quenched or enhanced on binding (Voss, 1993; Masui and Kuramitsu, 1998).

(3) the optical properties of the target may be modified on binding of the ligand, for example, the fluorescence of the target is quenched or enhanced on binding (Guixe et al., 1998; Qi and Grabowski, 1998)

(4) the optical properties of both target and ligand are modified on binding, for example, there can be a fluorescence resonance energy transfer (FRET) from target to ligand (or vice versa) resulting in emission at the “acceptor” emission wavelength when excitation is at the “donor” absorption wavelength (Heim & Tsien, 1996; Mahajan et al., 1998; Miyawaki et al., 1997).

The invention provides a method wherein a compound with the desired activity induces a change in the optical properties of the microcapsule, which enables the microcapsule
containing the compound and the microbeads contained therein to be identified, and optionally, sorted.

In an alternative embodiment, the invention provides a method wherein microbeads are analysed following pooling of the microcapsules into one or more common compartments. In this embodiment, a compound having the desired activity modifies the optical properties of the microbead which carried it (and which resides in the same microcapsule) to allow it to be identified, and optionally, sorted.

In this embodiment, it is not necessary for binding of the target to the ligand to directly induce a change in optical properties.

In this embodiment, if a ligand attached to the microbead has affinity for the target it will be bound by the target. At the end of the reaction, all of the microcapsules are combined, and all microbeads pooled together in one environment. Microbeads carrying compounds which modulate the binding activity can be identified by adding reagents that specifically bind to, or react specifically with, the target and thereby induce a change in the optical properties of the microbeads allowing their identification. For example, a fluorescently-labelled anti-target antibody can be used, or an anti-target antibody followed by a second fluorescently labelled antibody which binds the first.

In an alternative embodiment, the target can be attached to the microbeads by a variety of means familiar to those skilled in the art (see for example (Hermanson, 1996)). The ligand to be screened contains a feature - a tag. At the end of the reaction, all of the microcapsules are combined, and all microbeads pooled together in one environment. Microbeads carrying compounds which modulate binding can be identified by adding reagents that specifically bind to, or react specifically with, the “tag” and thereby induce a change in the optical properties of the microbeads allowing their identification. For example, a fluorescently-labelled anti-“tag” antibody can be used, or an anti-“tag” antibody followed by a second fluorescently labelled antibody which binds the first.

Fluorescence may be enhanced by the use of Tyramide Signal Amplification (TSA™) amplification to make the microbeads fluorescent (Sepp et al., 2002), as above.
(iii) SCREENING FOR REGULATION OF CATALYSIS

In an alternative embodiment, the invention provides a method wherein a compound with the desired activity induces a change in the optical properties of the microcapsule, which enables the microcapsule containing the compound and, optionally, the microbeads contained therein to be identified, and optionally, sorted. The optical properties of microcapsules can be modified by either:

(a) the substrate and product of the regulated reaction having different optical properties (many fluorogenic enzyme substrates are available commercially, see for example (Haugland, 1996 and www.probes.com) including substrates for glycosidases, phosphatases, peptidases and proteases, or

(b) the presence of reagents which specifically bind to, or react with, the product (or substrate) of the regulated reaction in the microcapsule and which thereby induce a change in the optical properties of the microcapsules allowing their identification.

A wide range of assays for screening libraries of compounds for those which modulate the activity of a target are based on detecting changes in optical properties and can be used to screen compounds according to this invention. Such assays are well known to those skilled in the art (see for example Haugland, 1996 and www.probes.com).

Alternatively, selection may be performed indirectly by coupling a first reaction to subsequent reactions that takes place in the same microcapsule. There are two general ways in which this may be performed. First, the product of the first reaction could be reacted with, or bound by, a molecule which does not react with the substrate(s) of the first reaction. A second, coupled reaction will only proceed in the presence of the product of the first reaction. A regulatory compound can then be identified by the properties of the product or substrate of the second reaction.

Alternatively, the product of the reaction being selected may be the substrate or cofactor for a second enzyme-catalysed reaction. The enzyme to catalyse the second reaction can be incorporated in the reaction mixture prior to microencapsulation. Only when the first reaction proceeds will the coupled enzyme generate an identifiable product.
This concept of coupling can be elaborated to incorporate multiple enzymes, each using as a substrate the product of the previous reaction. This allows for selection of regulators of enzymes that will not react with an immobilised substrate. It can also be designed to give increased sensitivity by signal amplification if a product of one reaction is a catalyst or a cofactor for a second reaction or series of reactions leading to a selectable product (for example, see (Johannsson, 1991; Johannsson and Bates, 1988). Furthermore an enzyme cascade system can be based on the production of an activator for an enzyme or the destruction of an enzyme inhibitor (see (Mize et al., 1989)). Coupling also has the advantage that a common screening system can be used for a whole group of enzymes which generate the same product and allows for the selection of regulation of complicated multi-step chemical transformations and pathways.

In an alternative embodiment, if the target is itself an enzyme, or regulates a biochemical process which is enzymatic, the microbead in each microcapsule may be coated with the substrate for the enzymatic reaction. The regulatory compound will determine the extent to which the substrate is converted into the product. At the end of the reaction the microbead is physically linked to the product of the catalysed reaction. When the microcapsules are combined and the reactants pooled, microbeads which were coated with activator compounds can be identified by any property specific to the product. If an inhibitor is desired, selection can be for a chemical property specific to the substrate of the regulated reaction.

It may also be desirable, in some cases, for the substrate not to be attached to the microbead. In this case the substrate would contain an inactive "tag" that requires a further step to activate it such as photoactivation (e.g. of a "caged" biotin analogue, (Pirrung and Huang, 1996; Sundberg et al., 1995)). After conversion of the substrate to product the "tag" is activated and the "tagged" substrate and/or product bound by a tag-binding molecule (e.g. avidin or streptavidin) attached to the microbead. The ratio of substrate to product attached to the nucleic acid via the "tag" will therefore reflect the ratio of the substrate and product in solution. A substrate tagged with caged biotin has been used to select for genes encoding enzymes with phosphotriesterase activity using a procedure based on compartmentalisation in microcapsules (Griffiths and Tawfik, 2003). The phosphotriesterase substrate was hydrolysed in solution in microcapsules containing active enzyme molecules, and after the reaction was completed, the caging group was
released by irradiation to allow the product to bind, *via* the biotin moiety, to microbeads to which the gene encoding the enzyme was attached.

After the microbeads and the contents of the microcapsules are combined, those microbeads coated with regulators can be selected by affinity purification using a molecule (e.g. an antibody) that binds specifically to the product or substrate as appropriate.

In an alternative embodiment, the invention provides a method wherein the microbeads are analysed following pooling of the microcapsules into one or more common compartments. Microbeads coated with regulator compounds can be identified using changes in optical properties of the microbeads. The optical properties of microbeads with product (or substrate) attached can be modified by either:

(1) the product-microbead complex having characteristic optical properties not found in the substrate-microbead complex, due to, for example;

   (a) the substrate and product having different optical properties (many fluorogenic enzyme substrates are available commercially (see for example Haugland, 1996 and www.probes.com) including substrates for glycosidases, phosphatases, peptidases and proteases, or

   (b) the substrate and product having similar optical properties, but only the product, and not the substrate binds to, or reacts with, the microbead;

(2) adding reagents which specifically bind to, or react with, the product (or substrate) and which thereby induce a change in the optical properties of the microbeads allowing their identification (these reagents can be added before or after breaking the microcapsules and pooling the microbeads). The reagents;

   (a) bind specifically to, or react specifically with, the product, and not the substrate, (*or vice versa*) if both substrate and product are attached to the microbeads, or

   (b) optionally bind both substrate and product if only the product, and not the substrate binds to, or reacts with, the microbeads (*or vice versa*).
In this scenario, the substrate (or one of the substrates) can be present in each microcapsule unlinked to the microbead, but has a molecular "tag" (for example biotin, DIG or DNP or a fluorescent group). When the regulated enzyme converts the substrate to product, the product retains the "tag" and is then captured in the microcapsule by the product-specific antibody. When all reactions are stopped and the microcapsules are combined, these microbeads will be “tagged” and may already have changed optical properties, for example, if the “tag” was a fluorescent group. Alternatively, a change in optical properties of “tagged” microbeads can be induced by adding a fluorescently labelled ligand which binds the “tag” (for example fluorescently-labelled avidin/streptavidin, an anti-“tag” antibody which is fluorescent, or a non-fluorescent anti-“tag” antibody which can be detected by a second fluorescently-labelled antibody).

(iv) SCREENING FOR COMPOUND SPECIFICITY/SELECTIVITY

Compounds with specificity or selectivity for certain targets and not others can be specifically identified by carrying out a positive screen for regulation of a reaction using one substrate and a negative screen for regulation of a reaction with another substrate. For example, two substrates, specific for two different target enzymes, are each labelled with different fluorogenic moieties. Each target enzymes catalyse the generation of a product with with a different fluorescence spectrum resulting in different optical properties of the microcapsules depending on the specificity of the compound for two targets.

(v) SCREENING USING CELLS

In the current drug discovery paradigm, validated recombinant targets form the basis of in vitro high-throughput screening (HTS) assays. Isolated proteins cannot, however, be regarded as representative of complex biological systems; hence, cell-based systems can provide greater confidence in compound activity in an intact biological system. A wide range of cell-based assays for drug leads are known to those skilled in the art. Cells can be compartmentalised in microcapsules, such as the aqueous microdroplets of a water-in-oil emulsion (Ghadessy, 2001). The effect of a compound(s) on a target can be determined by compartmentalising a cell (or cells) in a microcapsule together with a compound(s) and using an appropriate cell-based assay to identify those compartments containing compounds with the desired effect on the cell(s). The use of water-in-fluorocarbon emulsions may be particularly advantageous: the high gas dissolving
capacity of fluorocarbons can support the exchange of respiratory gases and has been reported to be beneficial to cell culture systems (Lowe, 2002).

(vi) FLOW CYTOMETRY

(vi) FLOW ANALYSIS AND SORTING

In a preferred embodiment of the invention the microcapsules or microbeads will be analysed and, optionally, sorted by flow cytometry. Many formats of microcapsule can be analysed and, optionally, sorted directly using flow cytometry.

In a highly preferred embodiment, microfluidic devices for flow analysis and, optionally, flow sorting (Fu, 2002) of microdroplets and microbeads will be used.

A variety of optical properties can be used for analysis and to trigger sorting, including light scattering (Kerker, 1983) and fluorescence polarisation (Rolland et al., 1985). In a highly preferred embodiment the difference in optical properties of the microcapsules or microbeads will be a difference in fluorescence and, if required, the microcapsules or microbeads will be sorted using a microfluidic or conventional fluorescence activated cell sorter (Norman, 1980; Mackenzie and Pinder, 1986), or similar device. Flow cytometry has a series of advantages:

(1) fluorescence activated cell sorting equipment from established manufacturers (e.g. Becton-Dickinson, Coulter, Cytomation) allows the analysis and sorting at up to 100,000 microcapsules or microbeads s\(^{-1}\).

(2) the fluorescence signal from each microcapsule or microbead corresponds tightly to the number of fluorescent molecules present. As little as few hundred fluorescent molecules per microcapsules or microbeads can be quantitatively detected;

(3) the wide dynamic range of the fluorescence detectors (typically 4 log units) allows easy setting of the stringency of the sorting procedure, thus allowing the recovery of the optimal number microcapsules or microbeads from the starting pool (the gates can be set to separate microcapsules or microbeads with small differences in fluorescence or to only separate out microcapsules or microbeads with large differences in fluorescence, dependant on the selection being performed);
(4) fluorescence-activated cell sorting equipment can perform simultaneous excitation and detection at multiple wavelengths (Shapiro, 1995), allowing positive and negative selections to be performed simultaneously by monitoring the labelling of the microcapsules or microbeads with two to thirteen (or more) fluorescent markers, for example, if substrates for two alternative targets are labelled with different fluorescent tags the microcapsules or microbeads can labelled with different fluorophores dependent on the target regulated.

If the microcapsules or microbeads are optically tagged, flow cytometry can also be used to identify the compound or compounds in the microcapsule or coated on the microbeads (see below). Optical tagging can also be used to identify the concentration of the compound in the microcapsule (if more than one concentration is used in a single experiment) or the number of compound molecules coated on a microbead (if more than one coating density is used in a single experiment). Furthermore, optical tagging can be used to identify the target in a microcapsule (if more than one target is used in a single experiment). This analysis can be performed simultaneously with measuring activity, after sorting of microcapsules containing microbeads, or after sorting of the microbeads.

(vii) MICROCAPSULE IDENTIFICATION AND SORTING

The invention provides for the identification and, optionally, the sorting of intact microcapsules where this is enabled by the sorting techniques being employed. Microcapsules may be identified and, optionally, sorted as such when the change induced by the desired compound either occurs or manifests itself at the surface of the microcapsule or is detectable from outside the microcapsule. The change may be caused by the direct action of the compound, or indirect, in which a series of reactions, one or more of which involve the compound having the desired activity leads to the change. For example, where the microcapsule is a membranous microcapsule, the microcapsule may be so configured that a component or components of the biochemical system comprising the target are displayed at its surface and thus accessible to reagents which can detect changes in the biochemical system regulated by the compound on the microbead within the microcapsule.

In a preferred aspect of the invention, however, microcapsule identification and, optionally, sorting relies on a change in the optical properties of the microcapsule, for
example absorption or emission characteristics thereof, for example alteration in the optical properties of the microcapsule resulting from a reaction leading to changes in absorbance, luminescence, phosphorescence or fluorescence associated with the microcapsule. All such properties are included in the term "optical". In such a case, microcapsules can be identified and, optionally, sorted by luminescence, fluorescence or phosphorescence activated sorting. In a highly preferred embodiment, flow cytometry is employed to analyse and, optionally, sort microcapsules containing compounds having a desired activity which result in the production of a fluorescent molecule in the microcapsule.

The methods of the current invention allow reagents to be mixed rapidly (in <2 ms), hence a spatially-resolved optical image of microcapsules in microfluidic network allows time resolved measurements of the reactions in each microcapsule. Microcapsules can, optionally, be separated using a microfluidic flow sorter to allow recovery and further analysis or manipulation of the molecules they contain. Advantageously, the flow sorter would be an electronic flow sorting device. Such a sorting device can be integrated directly on the microfluidic device, and can use electronic means to sort the microcapsules. Optical detection, also integrated directly on the microfluidic device, can be used to screen the microcapsules to trigger the sorting. Other means of control of the microcapsules, in addition to charge, can also be incorporated onto the microfluidic device.

In an alternative embodiment, a change in microcapsule fluorescence, when identified, is used to trigger the modification of the microbead within the compartment. In a preferred aspect of the invention, microcapsule identification relies on a change in the optical properties of the microcapsule resulting from a reaction leading to luminescence, phosphorescence or fluorescence within the microcapsule. Modification of the microbead within the microcapsules would be triggered by identification of luminescence, phosphorescence or fluorescence. For example, identification of luminescence, phosphorescence or fluorescence can trigger bombardment of the compartment with photons (or other particles or waves) which leads to modification of the microbead or molecules attached to it. A similar procedure has been described previously for the rapid sorting of cells (Keij et al., 1994). Modification of the microbead may result, for example, from coupling a molecular "tag", caged by a photolabile protecting group to the
microbeads: bombardment with photons of an appropriate wavelength leads to the removal of the cage. Afterwards, all microcapsules are combined and the microbeads pooled together in one environment. Microbeads coated with compounds exhibiting the desired activity can be selected by affinity purification using a molecule that specifically binds to, or reacts specifically with, the "tag".

(C) COMPOUND LIBRARIES

(i) PRIMARY COMPOUND LIBRARIES

Libraries of primary compounds can be obtained from a variety of commercial sources. The compounds in the library can be made by a variety of means well known to those skilled in the art. Optionally, compound libraries can be made by combinatorial synthesis using spatially resolved parallel synthesis or using split synthesis, optionally to generate one-bead-one-compound libraries. The compounds can, optionally, be synthesised on beads. These beads can be compartmentalised in microcapsules directly or the compounds released before compartmentalisation.

Advantageously, only a single type of compound, but multiple copies thereof is present in each microcapsule.

The compounds can, optionally, be connected to microbeads either covalently or non-covalently by a variety of means that will be familiar to those skilled in the art (see, for example, (Hermanson, 1996)).

Microbeads are available with a variety of surface chemistries from hydrophobic surfaces (e.g. plain polystyrene), to very hydrophilic surfaces imparted by a wide variety of functional surface groups: aldehyde, aliphatic amine, amide, aromatic amine, carboxylic acid, chloromethyl, epoxy, hydrazide, hydroxyl, sulfonate and tosyl. The functional groups permit a wide range of covalent coupling reactions, well known to those skilled in the art, for stable or reversible attachment of compounds to the microbead surface.

Advantageously, the compounds are attached to the microbeads via a cleavable linker. A variety of such linkers are familiar to those skilled in the art (see for example (Gordon and Balasubramanian, 1999)), including for example, linkers which can be cleaved photochemically and reversible covalent bonds which can be controlled by changing the
pH (e.g. imines and acylhydrazones), by adjusting the oxido-reductive properties (e.g. disulphides), or using an external catalyst (e.g. cross-metathesis and transamidation).

Advantageously, only a single type of compound, but multiple copies thereof is attached to each bead.

(ii) SECONDARY COMPOUND LIBRARIES

Secondary compound libraries are created by reactions between primary compounds in microcapsules. Secondary compounds can be created by a variety of two component, and multi-component reactions well known to those skilled in the art (Armstrong et al., 1996; Domling, 2002; Domling and Ugi, 2000; Ramstrom and Lehn, 2002).

To form secondary compound libraries by a two-component reaction, two sets of compounds are compartmentalised in microcapsules such that many compartments contain two or more compounds. Advantageously, the modal number of compounds per microcapsule is two. Advantageously, the microcapsules contain at least one type of compound from each set of compounds. Advantageously, the microcapsules contain one type of compound from each set of compounds. The secondary compounds are formed by chemical reactions between primary compounds from different sets. The secondary compound may be the result of a covalent or non-covalent reaction between the primary compounds.

A variety of chemistries, familiar to those skilled in the art, are suitable to form secondary compounds in two-component reactions. For example, reversible covalent bonds which can be controlled by changing the pH (e.g. imines and acylhydrazones), by adjusting the oxido-reductive properties (e.g. disulphides), or using an external catalyst (e.g. cross-metathesis and transamidation), can be used (Ramstrom and Lehn, 2002).

In a further embodiment, the method can also be used to create secondary compound libraries using three-component, four-component and higher order multi-component reactions. Three, four or more sets of compounds (as appropriate) are compartmentalised in microcapsules. The compounds are compartmentalised in microcapsules such that many compartments contain multiple compounds. Advantageously, the modal number of compounds per microcapsule is equal to the number of components in the reaction. Advantageously, the microcapsules contain at least one type of compound from each set
of compounds. Advantageously, the microcapsules contain one type of compound from each set of compounds. The secondary compounds are formed by chemical reactions between primary compounds from different sets. The secondary compound may be the result of covalent or non-covalent reactions between the primary compounds.

Examples of suitable multi-component reactions are the Strecker, Hantzsch, Biginelli, Mannich, Passerini, Bucherer-Bergs and Pauson-Khand three-component reactions and the Ugi four-component reaction (Armstrong et al., 1996; Domling, 2002; Domling and Ugi, 2000).

Secondary compound libraries may also be built using a scaffold molecule which is common to all the secondary compounds (Ramstrom and Lehn, 2002). This scaffold molecule may be compartmentalised into microcapsules together with the other primary compounds.

In a further embodiment, to form secondary compound libraries by a two-component reaction, two sets of compounds are attached to microbeads, advantageously to give only a single type of molecule per microbead. The microbeads are compartmentalised in microcapsules such that many compartments contain two or more microbeads. Advantageously, the modal number of beads per microcapsule is two. The compounds comprising at least one of the two sets are released from the microbeads. The secondary compounds are formed by chemical reactions between primary compounds from different sets. The secondary compound may be the result of a covalent or non-covalent reaction between the primary compounds.

In a further embodiment, the method can also be used to create secondary compound libraries using three-component, four-component and higher order multi-component reactions. Three, four or more sets of compounds (as appropriate) are attached to microbeads, advantageously to give only a single type of molecule per microbead. The microbeads are compartmentalised in microcapsules such that many compartments contain multiple microbeads. Advantageously, the modal number of beads per microcapsule is equal to the number of components in the reaction. The compounds comprising either all, or all bar one, of the sets are released from the microbeads. The secondary compounds are formed by chemical reactions between primary compounds.
from different sets. The secondary compound may be the result of covalent or non-covalent reactions between the primary compounds.

Advantageously, the same reversible covalent bond can be used to couple the primary compound to the microbead as is used to form the secondary compound.

Secondary compound libraries may also be built using a scaffold molecule which is common to all the secondary compounds (Ramstrom and Lehn, 2002). This scaffold molecule may be compartmentalised into microcapsules together with the microbeads.

(D) IDENTIFICATION OF COMPOUNDS

The compounds in microcapsules or on microbeads can be identified in a variety of ways. If the identified microcapsules are sorted (e.g. by using a fluorescence activated cell sorter - FACS) the compounds can be identified by by direct analysis, for example by mass-spectroscopy. If the compounds remain attached to beads isolated as a result of selection (for example by affinity purification) or sorting (for example using a FACS) they can also be identified by direct analysis, for example by mass-spectroscopy. The microcapsules or beads can also be tagged by a variety of means well known to those skilled in the art and the tag used to identify the compound attached to the beads (Czarnik, 1997). Chemical, spectrometric, electronic, and physical methods to encode the compounds may all be used. In a preferred embodiment microcapsules or beads have different optical properties and are thereby optically encoded. In a preferred embodiment encoding is based on microcapsules or beads having different fluorescence properties. In a highly preferred embodiment the microcapsules or beads are encoded using fluorescent quantum dots present at different concentrations in the microcapsule or bead (Han, 2001). Microcapsules flowing in an ordered sequence in a microfluidic channel can also be encoded (wholly or partially) by their sequence in the stream of microcapsules (positional encoding).

Advantageously, each compounds is present in different microcapsules at different concentrations (typically at concentrations varying from mM to nM) allowing the generation of a dose-response curve. Fusing microcapsules to give all possible permutations of several different substrate concentrations and compound concentrations would allow the determination of the mode of inhibition (e.g. competitive,
noncompetitive, uncompetitive or mixed inhibition) and inhibition constant ($K_i$) of an inhibitory compound. The concentration of the compounds in the microcapsules can be determined by, for example, optical encoding or positional encoding of the microcapsules or microbeads as above.

5 (E) IDENTIFICATION OF TARGETS

Advantageously, multiple different targets can be compartmentalised in microcapsules such that each microcapsule contains multiple copies of the same target. For example, multiple protein kinases, or multiple polymorphic variants of a single target, can be compartmentalised to allow the specificity of compounds to be determined. The identity of the target in a microcapsule can be determined by, for example, optical encoding or positional encoding of the microcapsules or microbeads as above.

Expressed in an alternative manner, there is provided a method for the synthesis and identification of compounds which bind to a target component of a biochemical system or modulate the activity of the target, comprising the steps of:

15 (a) compartmentalising two or more sets of primary compounds into microcapsules together with the target such that many compartments contain two or more primary compounds;

(b) forming secondary compounds in the microcapsules by chemical reactions between primary compounds from different sets; and

20 (c) identifying subsets of primary compounds which react to form secondary compounds which bind to or modulate the activity of the target.

There is also provided a method for the synthesis and identification of compounds which bind to a target component of a biochemical system or modulate the activity of the target, comprising the steps of:

25 (1) attaching two or more sets of primary compounds onto microbeads;

(2) compartmentalising the microbeads into microcapsules together with the target such that many compartments contain two or more microbeads;
(3) releasing the primary compounds from the microbeads;

(4) forming secondary compounds in the microcapsules by chemical reactions between primary compounds from different sets; and

(5) identifying subsets of primary compounds which react to form secondary compounds which bind to or modulate the activity of the target.

If the primary compounds react, not only with other primary compounds in the same compartment, but also with other microbeads in the compartment, the primary compounds which react together to form a secondary compound can be identified by direct analysis of the compounds present on a microbeads isolated as a result of selection or sorting. For example, if the primary compounds are linked to the beads via a disulphide bond when they are released in the compartment the primary compounds will react both with each other to form a secondary compound and with the sulphhydryl groups on the beads. Hence, if two beads are co-compartmentalised, each bead will end up carrying both primary compounds. After isolation of these beads both primary compounds which reacted to form the secondary compound can be identified.

(F) RAPID MIXING OF REAGENTS IN MICROCAPSULES

Advantageously, after fusion of microcapsules, the reagents contained in the fused microcapsule can be mixed rapidly using chaotic advection. By passing the droplets through channels that disrupt the laminar flow lines of the fluid within the droplets, their contents can be rapidly mixed, fully initiating any chemical reactions.

(G) SENSING MICROCAPSULE CHARACTERISTICS

In certain aspects of the invention, sensors are provided that can sense and/or determine one or more characteristics of the fluidic droplets, and/or a characteristic of a portion of the fluidic system containing the fluidic droplet (e.g., the liquid surrounding the fluidic droplet) in such a manner as to allow the determination of one or more characteristics of the fluidic droplets. Characteristics determinable with respect to the droplet and usable in the invention can be identified by those of ordinary skill in the art. Non-limiting
examples of such characteristics include fluorescence, spectroscopy (e.g., optical, infrared, ultraviolet, etc.), radioactivity, mass, volume, density, temperature, viscosity, pH, concentration of a substance, such as a biological substance (e.g., a protein, a nucleic acid, etc.), or the like.

In some cases, the sensor may be connected to a processor, which in turn, cause an operation to be performed on the fluidic droplet, for example, by sorting the droplet, adding or removing electric charge from the droplet, fusing the droplet with another droplet, splitting the droplet, causing mixing to occur within the droplet, etc., for example, as previously described. For instance, in response to a sensor measurement of a fluidic droplet, a processor may cause the fluidic droplet to be split, merged with a second fluidic droplet, sorted etc.

One or more sensors and/or processors may be positioned to be in sensing communication with the fluidic droplet. “Sensing communication,” as used herein, means that the sensor may be positioned anywhere such that the fluidic droplet within the fluidic system (e.g., within a channel), and/or a portion of the fluidic system containing the fluidic droplet may be sensed and/or determined in some fashion. For example, the sensor may be in sensing communication with the fluidic droplet and/or the portion of the fluidic system containing the fluidic droplet fluidly, optically or visually, thermally, pneumatically, electronically, or the like. The sensor can be positioned proximate the fluidic system, for example, embedded within or integrally connected to a wall of a channel, or positioned separately from the fluidic system but with physical, electrical, and/or optical communication with the fluidic system so as to be able to sense and/or determine the fluidic droplet and/or a portion of the fluidic system containing the fluidic droplet (e.g., a channel or a microchannel, a liquid containing the fluidic droplet, etc.). For example, a sensor may be free of any physical connection with a channel containing a droplet, but may be positioned so as to detect electromagnetic radiation arising from the droplet or the fluidic system, such as infrared, ultraviolet, or visible light. The electromagnetic radiation may be produced by the droplet, and/or may arise from other portions of the fluidic system (or externally of the fluidic system) and interact with the fluidic droplet and/or the portion of the fluidic system containing the fluidic droplet in such a manner as to indicate one or more characteristics of the fluidic droplet, for example, through absorption, reflection, diffraction, refraction, fluorescence, phosphorescence, changes in
polarity, phase changes, changes with respect to time, etc. As an example, a laser may be
directed towards the fluidic droplet and/or the liquid surrounding the fluidic droplet, and
the fluorescence of the fluidic droplet and/or the surrounding liquid may be determined.
"Sensing communication," as used herein may also be direct or indirect. As an example,
light from the fluidic droplet may be directed to a sensor, or directed first through a fiber
optic system, a waveguide, etc., before being directed to a sensor.

Non-limiting examples of sensors useful in the invention include optical or
electromagnetically-based systems. For example, the sensor may be a fluorescence
sensor (e.g., stimulated by a laser), a microscopy system (which may include a camera or
other recording device), or the like. As another example, the sensor may be an electronic
sensor, e.g., a sensor able to determine an electric field or other electrical characteristic.
For example, the sensor may detect capacitance, inductance, etc., of a fluidic droplet
and/or the portion of the fluidic system containing the fluidic droplet.

As used herein, a "processor" or a "microprocessor" is any component or device able to
receive a signal from one or more sensors, store the signal, and/or direct one or more
responses (e.g., as described above), for example, by using a mathematical formula or an
electronic or computational circuit. The signal may be any suitable signal indicative of
the environmental factor determined by the sensor, for example a pneumatic signal, an
electronic signal, an optical signal, a mechanical signal, etc.

(H) MATERIALS

A variety of materials and methods, according to certain aspects of the invention, can be
used to form any of the above-described components of the microfluidic systems and
devices of the invention. In some cases, the various materials selected lend themselves to
various methods. For example, various components of the invention can be formed from
solid materials, in which the channels can be formed via micromachining, film deposition
processes such as spin coating and chemical vapor deposition, laser fabrication,
photolithographic techniques, etching methods including wet chemical or plasma
processes, and the like. See, for example, Scientific American, 248:44-55, 1983 (Angell,
et al). In one embodiment, at least a portion of the fluidic system is formed of silicon by
etching features in a silicon chip. Technologies for precise and efficient fabrication of
various fluidic systems and devices of the invention from silicon are known. In another
embodiment, various components of the systems and devices of the invention can be formed of a polymer, for example, an elastomeric polymer such as polydimethylsiloxane ("PDMS"), polytetrafluoroethylene ("PTFE" or Teflon®), or the like.

Different components can be fabricated of different materials. For example, a base portion including a bottom wall and side walls can be fabricated from an opaque material such as silicon or PDMS, and a top portion can be fabricated from a transparent or at least partially transparent material, such as glass or a transparent polymer, for observation and/or control of the fluidic process. Components can be coated so as to expose a desired chemical functionality to fluids that contact interior channel walls, where the base supporting material does not have a precise, desired functionality. For example, components can be fabricated as illustrated, with interior channel walls coated with another material. Material used to fabricate various components of the systems and devices of the invention, e.g., materials used to coat interior walls of fluid channels, may desirably be selected from among those materials that will not adversely affect or be affected by fluid flowing through the fluidic system, e.g., material(s) that is chemically inert in the presence of fluids to be used within the device.

In one embodiment, various components of the invention are fabricated from polymeric and/or flexible and/or elastomeric materials, and can be conveniently formed of a hardenable fluid, facilitating fabrication via molding (e.g. replica molding, injection molding, cast molding, etc.). The hardenable fluid can be essentially any fluid that can be induced to solidify, or that spontaneously solidifies, into a solid capable of containing and/or transporting fluids contemplated for use in and with the fluidic network. In one embodiment, the hardenable fluid comprises a polymeric liquid or a liquid polymeric precursor (i.e. a "prepolymer"). Suitable polymeric liquids can include, for example, thermoplastic polymers, thermoset polymers, or mixture of such polymers heated above their melting point. As another example, a suitable polymeric liquid may include a solution of one or more polymers in a suitable solvent, which solution forms a solid polymeric material upon removal of the solvent, for example, by evaporation. Such polymeric materials, which can be solidified from, for example, a melt state or by solvent evaporation, are well known to those of ordinary skill in the art. A variety of polymeric materials, many of which are elastomeric, are suitable, and are also suitable for forming molds or mold masters, for embodiments where one or both of the mold masters is
composed of an elastomeric material. A non-limiting list of examples of such polymers includes polymers of the general classes of silicone polymers, epoxy polymers, and acrylate polymers. Epoxy polymers are characterized by the presence of a three-membered cyclic ether group commonly referred to as an epoxy group, 1,2-epoxide, or oxirane. For example, diglycidyl ethers of bisphenol A can be used, in addition to compounds based on aromatic amine, triazine, and cycloaliphatic backbones. Another example includes the well-known Novolac polymers. Non-limiting examples of silicone elastomers suitable for use according to the invention include those formed from precursors including the chlorosilanes such as methylchlorosilanes, ethylchlorosilanes, phenylchlorosilanes, etc.

Silicone polymers are preferred in one set of embodiments, for example, the silicone elastomer polydimethylsiloxane. Non-limiting examples of PDMS polymers include those sold under the trademark Sylgard by Dow Chemical Co., Midland, MI, and particularly Sylgard 182, Sylgard 184, and Sylgard 186. Silicone polymers including PDMS have several beneficial properties simplifying fabrication of the microfluidic structures of the invention. For instance, such materials are inexpensive, readily available, and can be solidified from a prepolymeric liquid via curing with heat. For example, PDMSs are typically curable by exposure of the prepolymeric liquid to temperatures of about, for example, about 65 °C to about 75 °C for exposure times of, for example, about an hour. Also, silicone polymers, such as PDMS, can be elastomeric and thus may be useful for forming very small features with relatively high aspect ratios, necessary in certain embodiments of the invention. Flexible (e.g., elastomeric) molds or masters can be advantageous in this regard.

One advantage of forming structures such as microfluidic structures of the invention from silicone polymers, such as PDMS, is the ability of such polymers to be oxidized, for example by exposure to an oxygen-containing plasma such as an air plasma, so that the oxidized structures contain, at their surface, chemical groups capable of cross-linking to other oxidized silicone polymer surfaces or to the oxidized surfaces of a variety of other polymeric and non-polymeric materials. Thus, components can be fabricated and then oxidized and essentially irreversibly sealed to other silicone polymer surfaces, or to the surfaces of other substrates reactive with the oxidized silicone polymer surfaces, without the need for separate adhesives or other sealing means. In most cases, sealing can be
completed simply by contacting an oxidized silicone surface to another surface without
the need to apply auxiliary pressure to form the seal. That is, the pre-oxidized silicone
surface acts as a contact adhesive against suitable mating surfaces. Specifically, in
addition to being irreversibly sealable to itself, oxidized silicone such as oxidized PDMS
can also be sealed irreversibly to a range of oxidized materials other than itself including,
for example, glass, silicon, silicon oxide, quartz, silicon nitride, polyethylene,
polystyrene, glassy carbon, and epoxy polymers, which have been oxidized in a similar
fashion to the PDMS surface (for example, via exposure to an oxygen-containing
plasma). Oxidation and sealing methods useful in the context of the present invention, as
well as overall molding techniques, are described in the art, for example, in an article

Another advantage to forming microfluidic structures of the invention (or interior, fluid-
contacting surfaces) from oxidized silicone polymers is that these surfaces can be much
more hydrophilic than the surfaces of typical elastomeric polymers (where a hydrophilic
interior surface is desired). Such hydrophilic channel surfaces can thus be more easily
filled and wetted with aqueous solutions than can structures comprised of typical,
unoxidized elastomeric polymers or other hydrophobic materials.

In one embodiment, a bottom wall is formed of a material different from one or more side
walls or a top wall, or other components. For example, the interior surface of a bottom
wall can comprise the surface of a silicon wafer or microchip, or other substrate. Other
components can, as described above, be sealed to such alternative substrates. Where it is
desired to seal a component comprising a silicote polymer (e.g. PDMS) to a substrate
(bottom wall) of different material, the substrate may be selected from the group of
materials to which oxidized silicone polymer is able to irreversibly seal (e.g., glass,
silicon, silicon oxide, quartz, silicon nitride, polyethylene, polystyrene, epoxy polymers,
and glassy carbon surfaces which have been oxidized). Alternatively, other sealing
techniques can be used, as would be apparent to those of ordinary skill in the art,
including, but not limited to, the use of separate adhesives, thermal bonding, solvent
bonding, ultrasonic welding, etc.
Various aspects and embodiments of the present invention are illustrated in the following examples. It will be appreciated that modification of detail may be made without departing from the scope of the invention.

EXAMPLES

Example 1. Microfluidic device for combinatorial chemistry and screening using in vitro compartmentalisation

A schematic representation of the microfluidic device is shown in Fig. 15. Microchannels are fabricated with rectangular cross-sections using rapid prototyping in poly(dimethylsiloxane) (PDMS) (McDonald and Whitesides, 2002) and rendered hydrophobic as (Song and Ismagilov, 2003). Syringe pumps were used to drive flows (Harvard Apparatus PHD 2000 Infusion pumps). For aqueous solutions, 250 μl Hamilton Gastight syringes (1700 series, TLL) with removeable needles of 27-gauge are used with 30-gauge Teflon tubing (Weico Wire and Cable). For the carrier fluid, 1 ml Hamilton Gastight syringes (1700 series, TLL) are used with 30-gauge Teflon needles with one hub from Hamilton (Song and Ismagilov, 2003). The carrier fluid is 9% (v/v) C₆F₁₄C₂H₄OH in perfluorodecaline (PFD) (Song et al., 2003). The microfluidic device consists of a series of interconnected modules. Each module has a specific function. These include modules that will produce droplets, fuse droplets, mix droplets, react droplets, detect droplets, and sort droplets (see Fig 16). In one example, droplets are made, consisting of different molecules or different concentrations of molecules. Droplets are made at rates of up to \(10^4\) sec⁻¹, and are made with a polydispersity of less than 1.5% and with sizes ranging from 1 μm to 100 μm. Each droplet is fused with a second droplet containing a second set of reactants, and is rapidly mixed to initiate the chemical reaction. This chemical reaction is allowed to proceed in each droplet by passing it through a delay channel. Each droplet is then fused with another droplet containing a second set of reactants, and is subsequently rapidly mixed to initiate the second set of chemical reactions. After the second reaction has proceeded in a delay module, the results of the reaction is determined using an optical sensor or other form of detection module. Finally, the desired droplets are sorted into two populations based on signal form the optical detection module, one population is kept for further processing and the other discarded. These and other modules can be used in this combination, or in other combinations.
**Droplet generation module:** We use a flow-focusing geometry to form the drops. A water stream is infused from one channel through a narrow constriction; counter propagating oil streams hydrodynamically focus the water stream reducing its size as it passes through the constriction as shown in Fig. 23A. This droplet generator can be operated in a flow regime that produces a steady stream of uniform droplets of water in oil. The size of the water droplets is controlled by the relative flow rates of the oil and the water; the viscous forces overcome surface tension to create uniform droplets. If the flow rate of the water is too high a longer jet of fluid passes through the orifice and breaks up into droplets further downstream; these droplets are less uniform in size. If the flow rate of the water is too low, the droplet breakup in the orifice becomes irregular again, producing a wider range of droplet sizes. While this emulsification technology is robust, it is limited to producing droplets of one size at any given flow rate; this droplet size is largely determined by the channel dimensions. Moreover, the timing of the droplet production cannot be controlled.

We overcome these limitations by incorporating electric fields to create an electrically addressable emulsification system. To achieve this, we apply high voltage to the aqueous stream and charge the oil water interface, as shown schematically in Fig. 23A. The water stream behaves as a conductor while the oil is an insulator; electrochemical reactions charge the fluid interface like a capacitor. At snap-off, charge on the interface remains on the droplet. In addition, the droplet volume, $V_d$, and frequency, $f$, can be tailored over nearly three orders of magnitude without changing the infusion rate of the oil or water. Droplet size and frequency are not independent; instead their product is determined by the infusion rate of the dispersed phase $Q_d = f V_d$. The droplet size decreases with increasing field strength, as shown in Figs. 23, B to E. The dependence of the droplet size on applied voltage for three different flow rates is summarized in Fig. 23F. At low applied voltages the electric field has a negligible effect, and droplet formation is driven exclusively by the competition between surface tension and viscous flow. By contrast, at high electric field strengths, there is a significant additional force on the growing drop, $F = qE$, where $q$ is the charge on the droplet. Since the droplet interface behaves as a capacitor, $q$ is proportional to the applied voltage, $V$. This leads to a $V^2$ dependence of the force, which accounts for the decrease in droplet size with increasing applied field shown in Fig. 23F. If the electric field becomes too large, the charged interface of the water
stream is repelled by the highly charged drops; this destabilizes the production and increases the variation in droplet size.

The electronic control afforded by the field-induced droplet formation provides an additional valuable benefit: it allows the phase of the droplet break-off to be adjusted within the production cycle. This is accomplished by increasing the field above the critical break-off field only at the instant the droplet is required. This provides a convenient means to precisely synchronize the production and arrival of individual droplets at specific locations.

**Droplet coalescer module:** An essential component in any droplet-based reaction-confinement system is a droplet coalescing module which combines two or more reagents to initiate a chemical reaction. This is particularly difficult to achieve in a microfluidic device because surface tension, surfactant stabilization, and drainage forces all hinder droplet coalescence; moreover, the droplets must cross the stream lines that define their respective flows and must be perfectly synchronized to arrive at a precise location for coalescence.

Use of electrostatic charge overcomes these difficulties; placing charges of opposite sign on each droplet and applying an electric field forces them to coalesce. As an example we show a device consisting of two separate nozzles that generate droplets with different compositions and opposite charges, sketched in Fig. 24A. The droplets are brought together at the confluence of the two streams. The electrodes used to charge the droplets upon formation also provide the electric field to force the droplets across the stream lines, leading to coalesce. Slight variations in the structure of the two nozzles result in slight differences in the frequency and phase of their droplet generation in the absence of a field. Thus the droplets differ in size even though the infusion rates are identical. Moreover, the droplets do not arrive at the point of confluence at exactly the same time. As a result the droplets do not coalesce as shown in Fig. 24B. By contrast, upon application of an electric field, droplet formation becomes exactly synchronized, ensuring that pairs of identically sized droplets each reach the point of confluence simultaneously. Moreover, the droplets are oppositely charged, forcing them to traverse the stream lines and contact each other, thereby causing them to coalesce, as shown in Fig. 24C. The remarkable synchronization of the droplet formation results from coupling of the break-
off of each of the pair of droplets as mediated by the electric field; the magnitude of the electric field varies as the separation between the leading edges of the two droplets changes and the frequency of droplet break-off is mode-locked to the electric field. A minimum charge is required to cause droplets to coalesce, presumably because of the stabilizing effects of the surfactant coating; this is clear from Fig. 24D which shows the voltage dependence of the percentage of drops that contact each other that actually coalesce.

**Droplet mixer module:** Rapid mixing is achieved through either successive iterations of translation and rotation, Fig. 25, or by coalescing drops along the direction parallel to the flow direction, Fig. 26.

**Droplet reactor/time delay module:** A delay line is used to provide a fixed time for a reaction. Two non-limiting examples of how this can be achieved are ‘single file’ and ‘large cross-section’ channels. The ‘single file’ delay line uses length to achieve a fixed reaction time. As this often results in exceptionally long channels, it is desirable to place spacer droplets of a third fluid, immiscible with both the carrier oil and the aqueous droplets inbetween aqueous droplet pairs. There is then an alternation between aqueous and non-aqueous droplets in a carrier oil. This is shown in Fig. 27A. A second possibility for achieving a long time delay is to use wide and deep channel having a ‘large cross-sectional area’ to slow the average velocity of the droplets. An example of this is shown in Fig. 27B.

**Recharging module:** The use of oppositely charged droplets and an electric field to combine and mix reagents is extremely robust, and 100% of the droplets coalesce with their partner from the opposite stream. However, after they coalesce the resultant drops carry no electrostatic charge. While it is convenient to charge droplets during formation, other methods must be employed in any robust droplet-based microfluidic system to recharge the mixed droplets if necessary for further processing. This is readily accomplished through the use of extensional flow to split neutral droplets in the presence of an electric field which polarizes them, resulting in two oppositely charged daughter droplets; this is sketched in Fig. 28A. The photomicrograph in Fig. 28B shows neutral droplets entering a bifurcation and splitting into charged daughter droplets. The dashed region in Fig. 28B is enlarged in Fig. 28C to illustrate the asymmetric stretching of the
charged droplets in the electric field. The vertical dashed lines indicate the edges of the electrodes where the droplets return to their symmetric spherical shape. The electric field also allows precision control of the droplet splitting providing the basis for a robust droplet division module which allows the splitting of the contents into two or more aliquots of identical reagent, facilitating multiple assays on the contents of the same microreactor.

**Detection module:** The detection module consists of an optical fiber, one or more laser, one or more dichroic beam splitter, bandpass filters, and one or more photo multiplying tube (PMT) as sketched in Fig 29.

**Sorting module:** The contents of individual droplets must be probed, and selected droplets sorted into discreet streams. The use of electrostatic charging of droplets provides a means for sorting that can be precisely controlled, can be switched at high frequencies, and requires no moving parts. Electrostatic charge on the droplets enables drop-by-drop sorting based on the linear coupling of charge to an external electric field. As an example, a T-junction bifurcation that splits the flow of carrier fluid equally will also randomly split the droplet population equally into the two streams, as shown in Fig. 30A. However, a small electric field applied at the bifurcation precisely dictates which channel the drops enter; a schematic of the electrode configuration is shown in Fig. 30B. Varying the direction of the field varies the direction of the sorted droplets as shown in Figs. 30C and 30D. The large forces that can be imparted on the droplets and the high switching frequency make this a fast and robust sorting engine with no moving parts; thus the processing rate is limited only by the rate of droplet generation.

**Example 2**

**Screening for protein tyrosine phosphatase 1B (PTP1B) inhibitors using microcapsules in microfluidic systems**

PTP1B is a negative regulator of insulin and leptin signal transduction. Resistance to insulin and leptin are hallmarks of type 2 diabetes mellitus and obesity and hence PTP1B is an attractive drug target for diabetes and obesity therapy (Johnson et al., 2002). Using a microfluidic device as described in Example 1, we describe how PTP1B inhibitors can be screened using microcapsules in a microfluidic system.
All water-soluble reagents are dissolved in (25 mM HEPES, pH 7.4, 125 mM NaCl, 1 mM EDTA), a buffer compatible with PTP1B activity. A solution of the target enzyme (human recombinant PTP1B, residues 1-322; Biomol Research Laboratories, Inc.) at 50 mU/ml and a solution of either a) 100 μM compound 2 (Fig. 17), which has a bis-difluoromethylene phosphonate and is a known PTP1B inhibitor (Johnson et al., 2002), or b) 100 μM hydrocinnamic acid (Aldrich), a compound that is not a PTP1B inhibitor are compartmentalised into microcapsules using the device. Each microcapsule containing target enzyme is fused with a microcapsule containing compound 2 or a microcapsule containing hydrocinnamic acid. Microcapsules containing either compound 2 or hydrocinnamic acid can be formed by switching between injection with syringes containing compound 2 and hydrocinnamic acid.

After microcapsule fusion the contents are rapidly mixed. After this point the microcapsules are run for up to 1 min through a 60 cm long microchannel (to allow inhibitor binding). This microchannel is then merged with a second microchannel containing aqueous microcapsules containing the fluorogenic PTP1B substrate 6,8-difluoro-4-methylumbelliferyl phosphate (DiFMUP) (Molecular Probes) in 25 mM HEPES, pH 7.4, 125 mM NaCl, 1 mM EDTA and the microcapsules fused pairwise. The fused microcapsules are then run for up to 2 min through a 60 cm long microchannel. Fluorescence of the microcapsules due to production of DiFMU (excitation/emission maxima 358/452 nm; blue fluorescence) is measured. Predominantly, microcapsules exhibiting blue fluorescence are those containing hydrocinnamic acid whereas microcapsules containing compound 2 exhibit low fluorescence due to inhibition of PTP1B.

**Example 3. Screening of PTP1B inhibitors from a compound library**

96 aqueous mixtures are made on ice (to prevent reaction). The first mixture contains 100 μM compound 2 (Fig. 17), which has a bis-difluoromethylene phosphonate and is a known PTP1B inhibitor (Johnson et al., 2002), and a pre-defined ratio of Qdot™ Streptavidin Conjugates with emmission maxima at 585 nm, 655 nm and 705 nm (Quantum Dot Corporation, Hayward CA) in a buffer compatible with PTP1B activity (25 mM HEPES, pH 7.4, 125 mM NaCl, 10% glycerol, 1 mM EDTA) (Doman et al., 2002). The 95 other aqueous mixtures are identical to the above but each contain one of
95 carboxylic acids from the Carboxylic Acid Organic Building Block Library (Aldrich) in place of compound 2, and different ratios of Qdot™ Streptavidin Conjugates with emission maxima at 585 nm, 655 nm and 705 nm. In all mixtures the concentration of the 705 nm Qdot™ Streptavidin Conjugates is 100 nM, and the concentrations of the 585 nm and 655 nm Qdot™ Streptavidin Conjugates is either 0, 11, 22, 33, 44, 55, 66, 77, 88 or 100 nM. Hence, there are 100 (10 x 10) permutations of Qdot™ Streptavidin Conjugate concentrations which allows the microcapsules containing each compound to have a unique fluorescence signature which is read by determining the fluorescence ratio of fluorescence at at 705 nm, 585 nm and 655 nm.

The 96 mixtures are distributed into 96 wells of a microtitre plate. Aliquots from each well of the plate are loaded sequentially into the microfluidic device described in Example 1 using thin tubes connected to the microfluidic device which are dipped into reservoirs containing the desired compounds, and capillary action is used to draw the desired compound from the reservoir into the microfluidic device. The mixtures are compartmentalised into microcapsules in the device. Each microcapsule is fused with another microcapsule containing the target enzyme (human recombinant PTP1B, residues 1-322; Biomol Research Laboratories, Inc.) at 5 mU/ml and rapidly mixed. After incubating for 10 min, at 37°C in a delay line the microcapsule is fused with a further microcapsule containing the fluorogenic PTP1B substrate 6,8-difuoro-4-methylumbelliferyl phosphate (DiFMUP) (Molecular Probes), and incubated at 37°C for 30 min. in a delay line. Inhibitors reduce the amount of non-fluorescent substrate (DiFMUP) converted to the dephosphorylated product (DiFMU; excitation/emission maxima 358/452 nm; blue fluorescence). Microcapsule fluorescence is then analysed. Predominantly, all microcapsules exhibited blue fluorescence due to dephosphorylation of DiFMUP by PTP1B except those with the Qdot fluorescence signature of the microcapsules containing compound 2.

Example 4. Attachment of a compound library to microbeads

5.5 μm diameter polystyrene microbeads that bear carboxylate functional groups on the surface are commercially available (www.luminexcorp.com) in an optically tagged form, as a result of incorporation of precise ratios of orange (585 nm), and red (>650 nm) fluorochromes (Fulton et al., 1997). A set of 100 such beads, each with a unique optical
signature (www.luminexcorp.com) are modified with an excess of ethylenediamine and EDC (1-ethyl-3-(3-dimethylaminopropyl)carbodiimide hydrochloride (Pierce) as (Hermanson, 1996) to create primary amino groups on the surface. The photocleavable linker 4-(4-hydroxymethyl-2-methoxy-5-nitrophenoxy)butanoic acid (NovaBiochem) (Holmes and Jones, 1995) is then attached to the beads by forming an amide bond using EDC as above. 100 different carboxylic acids from the Carboxylic Acid Organic Building Block Library (Aldrich) are then coupled to the beads, by reacting with the linker alcohol to form a carboxylate ester, each of the 100 different optically tagged beads being coupled to a different carboxylic acid, and each bead being derivatised with \(\sim 10^6\) molecules of carboxylic acid. Irradiation for 4 min on ice using a B100 AP 354 nm UV lamp (UVP) from a distance of \(\sim 5\) cm results in release of the compounds from the beads as carboxylic acids.

**Example 5. Screening for inhibitors of the enzyme protein tyrosine phosphatase 1B (PTP1B) using compounds attached to microbeads**

5.5 \(\mu\)m diameter polystyrene microbeads that bear carboxylate functional groups on the surface are commercially available (www.luminexcorp.com) in an optically tagged form, as a result of incorporation of precise ratios of orange (585 nm), and red (>650 nm) fluorochromes (Fulton et al., 1997). First, the carboxylate functional groups on the microbeads are converted to primary amines using ethylenediamine and EDC as in example 6. A phosphopeptide substrate for PTP1B, the undecapptide EGFR\(_{988-998}\) (DADEpYLIPQQG) (Zhang et al., 1993), is then coupled to both sets of microbeads via the surface amino groups using EDC. This peptide is made by solid phase synthesis on Sieber Amide resin (9-Fmoc-amino-xanthen-3-yloxy-Merrifield resin) (Novabiochem) with orthogonal protection on the side chain carboxylate groups using carboxylate-O-allyl esters. A linker comprised of tetradecanedioic acid is coupled to the N-terminus and the peptide cleaved from the beads using 1\% TFA to yield a peptide with a C-terminal amide. The peptide is coupled to the beads (using EDC) via the linker to give \(\sim 10^2\) peptides per bead. The remaining surface amino groups are then modified by attaching the photochemically cleavable linker 4-(4-hydroxymethyl-2-methoxy-5-nitrophenoxy)butanoic acid as in example 6. The protecting groups on the side chain carboxylates of the peptide are then removed using Pd(Ph\(_3\))\(/\)CHCl\(_3\)/HOAc/N-methyl morpholine. A first set of microbeads is derivatised with 3-(4-
difluorophosphonomethylphenyl)propanoic acid (compound 1, Fig. 17), a compound that is a known PTP1B inhibitor (Johnson et al., 2002). A second set of beads, with a distinct optical tag from the first set of beads, is derivatised with hydrocinnamic acid (Aldrich), a compound that is not a PTP1B inhibitor. In each case the compound is coupled by reacting with the linker alcohol to form a carboxylate ester as in example 6. Each microbead is derivatised with ~10^6 molecules (Fulton et al., 1997).

The microbeads are then screened using the microfluidic system outlined in Fig 15. The two sets of microbeads are mixed in ratios varying from 1:1000 to 1:1 (compound 1 beads: hydrocinnamic acid beads) and 10^8 total microbeads are mixed with the target enzyme (human recombinant PTP1B, residues 1-322; Biomol Research Laboratories, Inc.) at a concentration of 10 nM, on ice (to prevent reaction) in a buffer compatible with PTP1B activity (25 mM HEPES, pH 7.4, 125 mM NaCl, 10% glycerol, 1 mM EDTA) (Doman et al., 2002). Single beads and target enzyme (PTP1B) are then colocalised in microcapsules by forming microcapsules using the microfluidic system described in Example 1. The concentration of beads is such that most microcapsules contain one or no beads. Each microcapsule is fused with another microcapsule containing the target enzyme (human recombinant PTP1B, residues 1-322; Biomol Research Laboratories, Inc.) at 5 mU/ml and rapidly mixed. The compound is released photochemically (as in example 4). After incubating for 10 min, at 37°C in a delay line the microcapsule is fused with a further microcapsule containing the fluorogenic PTP1B substrate 6,8-difluoro-4-methylumbelliferyl phosphate (DiFMUP) (Molecular Probes), and incubated at 37°C for 30 min. in a delay line. Inhibitors reduce the amount of substrate converted to product (dephosphorylated peptide). The microcapsules are collected, cooled to 4°C and broken as (Griffiths and Tawfik, 2003) into 100 µM vanadate to stop the reaction (Harder et al., 1994). After labelling with an anti-substrate (anti-phosphotyrosine) antibody labelled with the green (530 nm) fluorochrome fluorescein isothiocyanate (mouse monoclonal IgG₂b PY20 (Santa Cruz) according to the manufacturer’s instructions, beads are analysed by 3-colour flow cytometry using a FACScan (Becton-Dickinson), FACScalibur (Becton-Dickinson) or MoFlo (Cytomation) flow cytometers to simultaneously determine the extent of inhibition and the compound on the beads. Predominantly, dephosphorylation of the peptide is only observed on those microbeads which were coated with PTP1B inhibitors, and not on other microbeads.
Example 6. Screening of PTP1B inhibitors from a compound library attached to microbeads

A set of 100 5.5 μm diameter polystyrene microbeads, bearing carboxylate functional groups on the surface and each with a unique optical signature (www.luminexcorp.com) as a result of incorporation of precise ratios of orange (585 nm), and red (>650 nm) fluorochromes (Fulton et al., 1997) are derivatised with a phosphopeptide substrate for PTP1B, the undecapaptide EGFR988,998 (DADEpYLIPQQG) (Zhang et al., 1993), and 100 different carboxylic acids, each attached via a photochemically cleavable linker, as in example 4. One of these carboxylic acids is 3-(4-difluorophosphonomethylphenyl) propanoic acid (compound 1, Fig. 17), a compound that is a known PTP1B inhibitor (Johnson et al., 2002). The other 99 carboxylic acids are from the Carboxylic Acid Organic Building Block Library (Aldrich) as example 4. Equal numbers of each of the 100 bead sets are then mixed and screened as for example 5. Predominantly, dephosphorylation of the peptide is only observed on those microbeads which were coated with the PTP1B inhibitor 3-(4-difluorophosphonomethylphenyl) propanoic acid (compound 1, Fig. 17), and not on microbeads coated with other compounds.

Example 7. Compartmentalisation of small molecules in a water-in-fluorocarbon emulsions.

Water-in-fluorocarbon emulsions containing 95% (v/v) perfluoroctyl bromide, 5% (v/v) phosphate buffered saline containing the molecule of interest in solution, and 2% (w/v) C8F17C11H22OP(O)[N(CH2CH2)2O]2 (F8H11DMP) as surfactant were formed essentially as (Sadtrler et al., 1996) by extrusion (15 times) through 14μm filters (Osmonics) or by homogenising for 5 min at 25,000 r.p.m. using an Ultra-Turrax T8 Homogenizer (IKA) with a 5 mm dispersing tool. Emulsions were made containing a series of small fluorescent molecules dissolved in the aqueous phase at concentrations from 100 μM to 2mM. These molecules, including calcein, texas red, fluorescein, coumarin 102, 7-hydroxycoumarin-3-carboxylic acid and 7-diethylamino-4-methyl coumarin (coumarin 1), had molecular weights from 203 to 625 Da and LogP values - calculated using SRC's LogKow/KowWin Program (Meylan and Howard, 1995) - ranging from −0.49 to 4.09.

Emulsions containing different coloured fluorochromes were mixed by vortexing. Compartmentalisation was observed by epifluorescence microscopy of the mixed
emulsions. No exchange between compartments was observed 24 hours after mixing (see Fig. 19).

Example 8. Compartmentalisation of small molecules in a water-in-fluorocarbon emulsions made using microfluidic systems. Water-in-fluorocarbon emulsions containing 95% (v/v) perfluoroctyl bromide, 5% (v/v) phosphate buffered saline containing the molecule of interest in solution, and 2% (w/v) C₆F₁₇CH₂OP(O)[N(CH₂CH₂)₂O]₂ (F₈H₁¹DMP) as surfactant were formed essentially using multiple droplet generation modules as described in Example 1. The aqueous phase at each of the nozzles contained a different small fluorescent molecules dissolved at concentrations from 100 µM to 2mM. These molecules, including calcein, texas red, fluorescein, coumarin 102, 7-hydroxycoumarin-3-carboxylic acid and 7-diethylamino-4-methyl coumarin (coumarin 1), had molecular weights from 203 to 625 Da and LogP values - calculated using SRC’s LogKow/KowWin Program (Meylan and Howard, 1995) - ranging from -0.49 to 4.09. Emulsions containing different coloured fluorochromes were mixed by combining the streams carrying the droplet having different fluorosers into a single stream containing all types of droplets. The stream carrying the collection of droplets then empties into a deep well on the device where the droplets can be stored in close proximity and monitored over time up to 24 hours. No cross contamination between the droplets is observed.

Example 9. Determining mode of inhibition and $K_i$ of PETG on β-galactosidase

Using a microfluidic device as described in Example 1, we demonstrate that the mode of inhibition of the enzyme E. coli β-galactosidase (LacZ), by phenylethyl β-D-thiogalactopyranoside (PETG), is competitive, and we show how we can obtain the inhibition constant ($K_i$) of PETG. In the enzyme inhibition assay, the rate of catalysis is determined by using a non-fluorescent substrate for LacZ, fluorescein mono-β-D-galactoside (FMG), and measuring the appearance of the fluorescent product, fluorescein (excitation 488 nm, emission 514 nm). All components of the LacZ inhibition assay are dissolved in assay buffer (10 mM MgCl₂, 50 mM NaCl, 1 mM DTT, 100 µg/ml BSA, 10 mM Tris-HCl, pH 7.9).

Leading into each droplet forming module (Fig. 15) are two Teflon tubes leading from syringe pumps. The channels leading from each tube merge to create a single flow before
entering the droplet forming module. The two syringes feeding into the first droplet forming module contain, (a) 50 μM PETG in assay buffer, and (b), assay buffer. The two syringes feeding into the second droplet forming module contain, (c) 100 nM LacZ in assay buffer. and (d), assay buffer. The two syringes feeding into the third droplet forming module contain, (e) 5 mM FMG in assay buffer, and (f), assay buffer. The final concentration of each component in each droplet is independently controllable by adjusting relative flow rates of each component and buffer solution while maintaining a constant combined flow rate from both syringes.

The first droplet fusion mixes the inhibitor (PETG) with the enzyme (LacZ). After the combined droplet has spent two minutes in a delay line it is fused with a third droplet containing the fluorogenic enzyme substrate (FMG). Finally, after all the components are mixed the reaction is observed by measuring fluorescence of individual droplets or by integrating fluorescent light from droplets with the same concentration of each component during 10-second exposure time at multiple points in the second 10 min long delay line. Each fluorescence intensity value at different positions is proportional to the amount of product at different reaction times. Rate of product formation is linear during initial reaction time and initial rate (v) can be determined from linear fitting. Data from the repeated measurement at different concentration of FMG and PETG are expressed in a Lineweaver-Burk plot (1/v vs. 1/[S]; where [S] = substrate concentration). The same y-intercept values at different concentration of PETG show that the mode of PETG inhibition is competitive. In competitive inhibition, each slope divided by the y-intercept represents an apparent Michaelis-Menten constant that is a linear function of the concentration of inhibitor. The y-intercept in a graph of apparent Michaelis-Menten constant versus competitive inhibitor concentration gives the Michaelis-Menten constant, and the inverse of its slope multiplied by the y-intercept is Ki. Using the following conditions (in the final fused microcapsule), 30 nM LacZ, 0 to 13 μM PETG and 10 to 700 μM FMG the Km of FMG for LacZ can be determined to within 20% of the previously published value (118 μM; Huang, 1991), and the Ki of PETG for LacZ can be determined to be within the range of the previously published value (0.98 μM; Huang, 1991).
Example 10

Synthesis of secondary compounds in emulsion microcapsules and screening for PTP1B inhibition in microfluidic systems

Using a microfluidic device as described in Example 1, we describe how PTP1B inhibitors can be synthesised and screened using microcapsules in a microfluidic system.

All water-soluble reagents are dissolved in (25 mM HEPES, pH 7.4, 125 mM NaCl, 1 mM EDTA), a buffer compatible with PTP1B activity. A compound which is a primary amine is compartmentalised into microcapsules using the device. A second solution, of a compound which is an aldehyde is also compartmentalised into microcapsules using the device. The amines and aldehydes can either a) contain a difluoromethylene phosphonate moiety (Fig. 22, compounds A and B), or b) contain no difluoromethylene phosphonate moiety. Each microcapsule containing a primary amine is fused with a microcapsule containing an aldehyde. Microcapsules containing compounds with and without difluoromethylene phosphonate moieties can be formed by switching between injection with syringes containing amines or aldehydes with or without a difluoromethylene phosphonate moiety.

After microcapsule fusion the contents are rapidly mixed and the microcapsules pass down a delay line. This allows the amine and the aldehyde to react together by formation of a Schiff base to create a secondary compound and allows inhibitors to bind to PTP1B.

Each microcapsules are then fused with a further microcapsule containing a solution of the target enzyme (human recombinant PTP1B, residues 1-322; Biomol Research Laboratories, Inc.) at 50 mU/ml, and the fluorogenic PTP1B substrate 6,8-difluoro-4-methylumbelliferyl phosphate (DiFMUP) (Molecular Probes). The fused microcapsules then run along a further delay line. Fluorescence of the microcapsules due to production of DiFMU (excitation/emission maxima 358/452 nm; blue fluorescence) is measured.

Predominantly, when the amine and aldehyde concentrations are low (<100 μM) inhibition of PTP1B activity is only observed in microcapsules containing both an amine with a difluoromethylene phosphonate moiety (compound A), and an aldehyde with a difluoromethylene phosphonate moiety (compound B). This is because the Schiff base formed in these microcapsules (compound C) contains bis-difluoromethylene
phosphonate and is a much more potent PTP1B inhibitor than a molecule with a single difluoromethylene phosphonate moiety.

Predominantly, when the amine and aldehyde concentrations are high (>100 μM) inhibition of PTP1B activity is observed in microcapsules containing either an amine with a difluoromethylene phosphonate moiety (compound A, or an aldehyde with a difluoromethylene phosphonate moiety (compound B), or both, but not in other microcapsules. This is because at higher concentrations molecules with either a single difluoromethylene phosphonate moiety or a bis-difluoromethylene phosphonate (compound C, Fig. 22) can inhibit PTP1B.

Example 11. Synthesis of a library of 2304 secondary compounds in emulsion microcapsules and screening of PTP1B inhibition in microfluidic systems

96 aqueous mixtures are made in a buffer compatible with PTP1B activity (25 mM HEPES, pH 7.4, 125 mM NaCl, 10% glycerol, 1 mM EDTA) (Doman et al., 2002) and containing the target enzyme (human recombinant PTP1B, residues 1-322; Biomol Research Laboratories, Inc.) at a concentration of 5 mU/ml. The first 48 mixtures each contain a unique compound containing a primary amine. One of these compounds (compound A, Fig. 22) contains a difluoromethylene phosphonate moiety. The second 48 mixtures of microbeads each contain a unique compound containing an aldehyde. One of these compounds (compound B, Fig. 22) contains a difluoromethylene phosphonate moiety.

The 96 mixtures are distributed into 96 wells of a microtitre plate. Aliquots from each well of the plate are loaded sequentially into the microfluidic device described in Example 1 using thin tubes connected to the microfluidic device which are dipped into reservoirs containing the desired compounds, and capillary action is used to draw the desired compound from the reservoir into the microfluidic device. The mixtures are compartmentalised into microcapsules in the device.

Each microcapsule containing an amine is fused with a microdroplet containing an aldehyde and incubated for 10 min, at 37°C in a delay line. The amine and the aldehyde react together by forming a Schiff base, resulting in the creation of a new molecule (an imine) in solution. The microcapsule is then fused with a further microcapsule containing
the fluorogenic PTP1B substrate 6,8-difluoro-4-methylumbelliferyl phosphate (DiFMUP) (Molecular Probes), and incubated at 37°C for 30 min. in a delay line. Inhibitors reduce the amount of non-fluorescent substrate (DiFMUP) converted to the dephosphorylated product (DiFMU; excitation/emission maxima 358/452 nm; blue fluorescence). Microcapsule fluorescence is then analysed.

Microcapsules containing a primary compound which is itself a PTP1B inhibitor, or which reacts with another primary compound to form a second inhibitor are identified as little substrate has been converted to product. When the compounds are present in the microcapsules at high concentration, the identified microcapsules where little substrate has been converted to product include those carrying compounds containing a difluoromethylene phosphonate moiety. When the compounds are present in the microcapsules at low concentration, the concentration of the compounds containing a difluoromethylene phosphonate moieties in the microcapsules is insufficient to efficiently inhibit PTP1B (see example 10). However, in microcapsules where two primary compounds have reacted to form an imine containing a bis-difluoromethylene phosphonate moiety, which is a highly potent PTP1B inhibitor (compound C, Fig. 22), this inhibits conversion of the PTP1B substrate to product and little fluorescence is observed.

Example 12

Synthesis of secondary compounds in emulsion microcapsules and screening for PTP1B inhibition using compounds attached to microbeads in microfluidic systems

5.5 μm diameter polystyrene microbeads that bear carboxylate functional groups on the surface are commercially available (www.luminexcorp.com) in an optically tagged form, as a result of incorporation of precise ratios of orange (585 nm), and red (>650 nm) fluorochromes (Fulton et al., 1997). First, the carboxylate functional groups on the microbeads are converted to primary amines using ethylenediamine and EDC as in example 4. A phosphopeptide substrate for PTP1B, the undecapaptide EGFR_{988-998} (DADEpYLIPQQG) (Zhang et al., 1993), is then coupled to both sets of microbeads via the surface amino groups using EDC and the protecting groups on the side chain carboxylates of the peptide removed as in example 5. A first set of microbeads (set 1) is reacted with succinimidyl p-formylbenzoate to convert the surface amino groups to
aldehydes. A second set of microbeads (set 2), with a distinct optical tag from the first set of microbeads, is left unreacted (i.e. with primary amines on the surface).

The first set of microbeads (set 1), are then reacted with a compound containing a difluoromethylene phosphonate moiety and a primary amine (compound A, Fig. 22) via reaction with the surface aldehyde groups to form a Schiff base. The second set of microbeads (set 2), with a distinct optical tag from the first set of beads, are reacted with a compound containing a difluoromethylene phosphonate moiety and an aldehyde (compound B, Fig. 22) via reaction of the aldehyde with the surface amine groups to form a Schiff base. The formation of Schiff bases is enhanced by reaction at alkaline pH (i.e. pH 9-10). Microbeads coated with compounds at various densities are created.

The two sets of microbeads are separately suspended in a buffer compatible with PTP1B activity (25 mM HEPES, pH 7.4, 125 mM NaCl, 10% glycerol, 1 mM EDTA) (Doman et al., 2002). Each set of microbeads is compartmentalised into microcapsules in the device described in Example 1. The number of microbeads is varied such that, at one extreme, most microcapsules contain one or no beads, and at the other, the majority of microcapsules contain two or more microbeads. Each microcapsule containing a set 1 microbead is fused with a microcapsule containing a set 2 microbead and incubated for 10 min, at 37°C in a delay line. The Schiff base is a relatively labile, reversible interaction, readily hydrolysed at neutral pH, resulting in release of compounds from the beads. In microcapsules containing a microbead from both set 1 and set 2, the compounds released from the microbeads can react with each other, forming a Schiff base and creating a new molecule in solution. This new molecule (Fig. 22, compound C) contains a bis-difluoromethylene phosphonate moiety and has significantly more potency as a PTP1B inhibitor than compounds with a single difluoromethylene phosphonate moiety (see Fig. 22). The microcapsule is then fused with a further microcapsule containing the target enzyme (human recombinant PTP1B, residues 1-322; Biomol Research Laboratories, Inc.) at a concentration of 5 mU/ml in 25 mM HEPES, pH 7.4, 125 mM NaCl, 10% glycerol, 1 mM EDTA, and incubated at 37°C for 30 min. in a delay line. Inhibitors reduce the amount of substrate converted to product (dephosphorylated peptide). The microcapsules are collected, cooled to 4°C, and broken into 100 µM vanadate to stop the reaction (Harder et al., 1994). After labelling with an anti-substrate (anti-phosphotyrosine) antibody labelled with the green (530 nm) fluorochrome fluorescein
isothiocyanate (mouse monoclonal IgG₂b PY20 (Santa Cruz) according to the manufacturer’s instructions, beads are analysed by 3-colour flow cytometry using a FACScan (Becton-Dickinson), FACScalibur (Becton-Dickinson) or MoFlo (Cytomation) flow cytometers to simultaneously determine the extent of inhibition and the compound on the beads. With low microbead numbers, most microcapsules contain only a single or no microbeads and PTP1B inhibition is only detected on beads coated with a high density of inhibitor, when the concentration of inhibitor released into solution in each microcapsule is sufficiently high for effective inhibition. In contrast, when the bead numbers are higher, many microbeads are detected where little substrate has been converted to product, even when the microbeads are coated with inhibitor at low density. This is due to the formation of a highly potent PTP1B inhibitor (Fig. 22, compound C) containing a bis-difluoromethylene phosphonate moiety in microcapsules containing a microbead each from set 1 and set 2.

Example 13

Synthesis of a library of 2500 secondary compounds in emulsion microcapsules and screening for PTP1B inhibition using compounds attached to microbeads in microfluidic systems

A set of 100 5.5 μm diameter polystyrene microbeads, bearing carboxylate functional groups on the surface and each with a unique optical signature (www.luminexcorp.com) as a result of incorporation of precise ratios of orange (585 nm), and red (>650 nm) fluorochromes (Fulton et al., 1997) are modified to convert the carboxylate functional groups to primary amines as in example 4, then derivatised with a phosphopeptide substrate for PTP1B, the undecapaptide EGFR_{988-998} (DADEpYLPQQG) (Zhang et al., 1993), as in example 5. The first 50 sets of microbeads are reacted to convert a proportion of the surface carboxyl groups to aldehydes as in example 10. The second 50 sets of microbeads are left unreacted (i.e. with primary amines on the surface).

The first 50 sets of microbeads are each reacted with a unique compound containing a primary amine via reaction with the surface aldehyde groups to form a Schiff base which links the compounds to the beads. One of these compounds (compound A, Fig. 22) contains a difluoromethylene phosphonate moiety. The second 50 sets of microbeads are each reacted with a unique compound containing an aldehyde via reaction with the
surface amine groups to form a Schiff base which links the compounds to the beads. One of these compounds (compound B, Fig. 22) contains a difluoromethylene phosphonate moiety. The formation of Schiff bases is enhanced by reaction at alkaline pH (i.e. pH9-10).

The 50 sets of microbeads which were reacted with primary amines (amine microbeads) are pooled and suspended in a buffer compatible with PTP1B activity (25 mM HEPES, pH 7.4, 125 mM NaCl, 10% glycerol, 1 mM EDTA) (Doman et al., 2002). The 50 sets of microbeads which were reacted with aldehydes (aldehyde microbeads) are pooled and suspended in the same buffer. The amine microbeads and the aldehyde microbeads are compartmentalised into microcapsules in the device described in Example 1. The number of microbeads is set such that the majority of microdroplets contain a single microbead. Each microcapsule containing an amine microbead is fused with a microcapsule containing an aldehyde microbead and incubated for 10 min, at 37°C in a delay line. The microcapsule is then fused with a further microcapsule containing the target enzyme (human recombinant PTP1B, residues 1-322; Biomol Research Laboratories, Inc.) at a concentration of 5 mU/ml in 25 mM HEPES, pH 7.4, 125 mM NaCl, 10% glycerol, 1 mM EDTA, and incubated at 37°C for 30 min. in a delay line. The Schiff base is a relatively labile, reversible interaction, readily hydrolysed at neutral pH, resulting in release of compounds from the beads. In microcapsules containing a microbead from one of the first 50 sets and a microbead from one of the second 50 sets, the compounds released from the microbeads can react with each other, forming a Schiff base and creating a new molecule in solution. Inhibitors reduce the amount of substrate converted to product (dephosphorylated peptide). The microcapsules are collected, cooled to 4°C, and broken into 100 µM vanadate to stop the reaction (Harder et al., 1994). After labelling with an anti-substrate (anti-phosphotyroisine) antibody labelled with the green (530 nm) fluorochrome fluorescein isothiocyanate (mouse monoclonal IgG₂b PY20 (Santa Cruz) according to the manufacturer’s instructions, beads are analysed by 3-colour flow cytometry using a FACScan (Becton-Dickinson), FACScalibur (Becton-Dickinson) or MoFlo (Cytomation) flow cytometers to simultaneously determine the extent of inhibition and the compound on the beads.

Beads which were coated with a primary compound which is itself a PTP1B inhibitor, or which reacts with another primary compound released from another co-
compartmentalised bead to form a second inhibitor are identified as little substrate has been converted to product. The identified beads where as little substrate has been converted to product include those carrying compounds containing a difluoromethylene phosphonate moiety. When the microbeads are coated with compounds at low density the concentration of the released compounds containing a difluoromethylene phosphonate moieties in the microcapsules is insufficient to efficiently inhibit PTP1B (see example 12). However in microcapsules containing two microbeads, one from the first set of 50 beads and one from the second set of 50 beads, and where each microbead carries a molecule with a difluoromethylene phosphonate moiety, the released molecules can form a highly potent PTP1B inhibitor (compound C, Fig. 22) containing a bis-difluoromethylene phosphonate moiety in the microcapsules which inhibits conversion of the PTP1B substrate to product.

All publications mentioned in the above specification, and references cited in said publications, are herein incorporated by reference. Various modifications and variations of the described methods and system of the invention will be apparent to those skilled in the art without departing from the scope and spirit of the invention. Although the invention has been described in connection with specific preferred embodiments, it should be understood that the invention as claimed should not be unduly limited to such specific embodiments. Indeed, various modifications of the described modes for carrying out the invention which are obvious to those skilled in molecular biology or related fields are intended to be within the scope of the following claims.
Claims

1. A method for preparing a repertoire of compounds comprising the steps of:

(a) compartmentalising two or more sets of primary compounds into microcapsules; such that a proportion of the microcapsules contains multiple copies of one or more compounds representative of each of said sets, and wherein said one or more compounds form a subset of the set of primary compounds;

(b) forming secondary compounds in the microcapsules by chemical reactions between primary compounds from different sets; wherein one or more of steps (a) and (b) are performed under microfluidic control.

2. A method according to claim 1, wherein the subset of primary compounds constitutes 10% or less of the set of primary compounds.

3. A method according to claim 2, wherein the subset of primary compounds constitutes 1% or less of the set of primary compounds.

4. A method according to claim 3, wherein the subset of primary compounds is a single compound.

5. A method according to claim 1, wherein, in step (a), the modal number of different primary compounds per compartment will be equivalent to the number of primary compounds forming the secondary compound in step (b).

6. A method according to claim 1, wherein step (a) comprises forming separate emulsion compartments comprising primary compounds and mixing the emulsion compartments to form an emulsified set of primary compounds wherein a subset of the set of primary compounds is represented in multiple copies in any one microcapsule.

7. A method according to claim 1, wherein step (a) comprises

(a) attaching the set of primary compounds onto microbeads, such that only a subset of the set of primary compounds is represented on any one microbead; and
(b) compartmentalising the microbeads into microcapsules;

such that a subset of the set of primary compounds is represented in multiple copies in any one microcapsule; wherein one or more of steps (a) and (b) are performed under microfluidic control.

8. A method according to claim 1, wherein at least one set of primary compounds comprises a repertoire of different compounds.

9. A method according to claim 1, wherein one of the sets of primary compounds consists of a single compound.

10. A method according to claim 7, wherein the compounds are attached to the beads non-covalently.

11. A method according to claim 7, wherein the compounds are attached to the beads covalently.

12. A method according to claim 7, wherein the compounds are attached to the microbeads by reversible physical or chemical mechanisms.

13. A method according to claim 11, wherein the compounds are attached to the microbeads by photochemically cleavable linkers.

14. A method for identifying primary compounds which react together to form secondary compounds capable of binding to or modulating the activity of a target, comprising the steps of:

20 (a) compartmentalising two or more sets of primary compounds into microcapsules; such that a proportion of the microcapsules contains two or more compounds;

(b) forming secondary compounds in the microcapsules by chemical reactions between primary compounds from different sets; and

25 (c) identifying subsets of primary compounds which react to form secondary compounds which bind to or modulate the activity of the target; wherein
one or more of steps (a) and (b) and (c) are performed under microfluidic control.

15. A method for synthesising compounds with enhanced ability to bind to or modulate the activity of the target, comprising the steps of:

(a) compartmentalising into microcapsules subsets of primary compounds identified in step (c) of the second aspect of the invention and, optionally, compartmentalising additional sets of primary compounds;

(b) forming secondary compounds in the microcapsules by chemical reactions between primary compounds from different sets; and

(c) identifying subsets of primary compounds which react to form secondary compounds which bind to or modulate the activity of the target; wherein one or more of steps (a) and (b) and (c) are performed under microfluidic control.

16. A method according to claim 15, wherein steps (a) to (c) are iteratively repeated, such that after the first cycle, step (a) comprises compartmentalising subsets of primary compounds identified in step (c) into microcapsules and, optionally, compartmentalising additional sets of compounds.

17. A method for identifying individual compounds which bind to or modulate the activity of the target, comprising the steps of:

(a) compartmentalising into microcapsules a primary compound identified in step (c) of the second or third aspect of the invention and additional sets of primary compounds;

(b) forming secondary compounds in the microcapsules by chemical reactions between primary compounds from different sets; and

(c) identifying subsets of primary compounds which react to form secondary compounds which bind to or modulate the activity of the target; wherein one or more of steps (a) and (b) and (c) are performed under microfluidic control.
18. A method according to claim 14, wherein the activity of the target is a binding activity.

19. A method according to claim 14, wherein the activity of the target is a catalytic activity.

20. A method according to claim 14, wherein the secondary compound reacts with the target to generate a reaction product.

21. A method according to claim 14, wherein the target is compartmentalised into microcapsules together with the compounds.

22. A method according to claim 14, wherein a scaffold molecule is compartmentalised into microcapsules together with the compounds.

23. A method according to claim 14, wherein the compounds are attached to beads, and in step (a) the primary molecules are released from the beads and react with other beads in the compartment to facilitate the identification of the primary compounds which react to form a secondary compounds which bind to and modulate the activity of the target in step (c).

24. A method according to claim 23, wherein the compound having a desired activity causes a change in the microcapsule or microbead which allows the microcapsule or microbead to be identified, sorted or selected.

25. A method according to claim 23, wherein the activity of the compound within the microcapsule results, directly or indirectly, in the modification of the microcapsule or microbead to enable the isolation of the microcapsule or microbead.

26. A method according to claim 23, wherein the primary compounds and the target are bound to microbeads, the target is a ligand and the secondary compound within the microcapsule binds, directly or indirectly, to said ligand to enable the isolation of the microbead.

27. A method according to claim 23, wherein microbeads are isolated by affinity purification.
28. A method according to claim 14, wherein a substrate is present in the microcapsules and the desired activity of the compound within the microcapsule results, directly or indirectly, in the regulation of conversion of said substrate into product.

29. A method according to claim 28, wherein the substrate is converted into the product by the catalytic action of the target.

30. A method according to claim 28, wherein the substrate and the product have different optical properties.

31. A method according to claim 30, wherein the substrate and product have different fluorescent properties.

32. A method according to claim 28, wherein the primary compound and the substrate are bound to a microbead, and the desired activity of the secondary compound within the microcapsule results, directly or indirectly, in the regulation of conversion of said substrate into a product which remains part of the microbead and enables its identification and, optionally, isolation.

33. A method according to claim 32, wherein the product and, optionally, the unreacted substrate are subsequently complexed with the microbead in the microcapsule.

34. A method according to claim 28, wherein the desired activity enhances the conversion of substrate into product.

35. A method according to claim 28, wherein the desired activity inhibits the conversion of substrate into product.

36. A method according to claim 28, wherein the compound having a desired activity causes a change in the microcapsule which allows the microcapsule to be identified, sorted or selected.

37. A method according to claim 28, wherein the modification of the target within the microcapsule induces a change in the optical properties of the microcapsule.
38. A method according to claim 24, wherein the modification of the microbead enables it to be further modified outside the microcapsule so as to induce a change in its optical properties.

39. A method according to claim 24, wherein the change in optical properties of the microbead is due to binding of a compound with distinctive optical properties to the microbead.

40. A method according to claim 24, wherein the change in optical properties of the microbead is due to binding of a target with distinctive optical properties by the compound.

41. A method according to claim 24, wherein the change in optical properties of the microbead is due to a change in the optical properties of the compound when bound to target.

42. A method according to claim 24, wherein the change in optical properties of the microbead is due to a change in the optical properties of the target when bound by the compound.

43. A method according to claim 24, wherein the change in optical properties of the microbead is due to a change in the optical properties of both target and compound on binding.

44. A method according to claim 24, wherein the compound acts to cause a change in the target, and the change in optical properties of the microbead is due to the different optical properties of the target and the product of the action of the compound on the target.

45. A method according to claim 24, wherein the compound acts to cause a change in the target without altering its optical properties, but only the product of the action, and not the target, binds to, or reacts with, the microbead, thereby changing the optical properties of the microbead.

46. A method according to claim 24, wherein further reagents specifically bind to, or specifically react with, the product (and not the substrate) of the regulated reaction, which is attached to the microbead, thereby altering the optical properties of the microbead.
47. A method according to claim 24, wherein further reagents specifically bind to, or specifically react with, the substrate (and not the product) of the regulated reaction, which is attached to the microbead, thereby altering the optical properties of the microbead.

48. A method according to claim 24, wherein the compound in a microcapsule is identified by a difference in the optical properties of the microcapsule.

49. A method according to claim 48 wherein the difference in the optical properties of the microcapsule is a difference in fluorescence.

50. A method according to claim 49 wherein the difference in the fluorescence of the microcapsule is due to the presence of quantum dots.

51. A method according to claim 24, wherein the compounds are present in different microcapsules at different concentrations.

52. A method according to claim 51, wherein the concentration of the compound in a microcapsule is identified by a difference in the optical properties of the microcapsule.

53. A method according to claim 52, wherein the difference in the optical properties of the microcapsule is a difference in fluorescence.

54. A method according to claim 53, wherein the difference in the fluorescence of the microcapsule is due to the presence of quantum dots.

55. A method according to claim 24 wherein the compound on a microbead is identified by a difference in the optical properties of the microbead.

56. A method according to claim 55 wherein the difference in the optical properties of the microbead is a difference in fluorescence.

57. A method according to claim 56 wherein the difference in the fluorescence of the microbead is due to the presence of quantum dots.

58. A method according to claim 24, wherein a second activity of a compound results in a change in the microbead or the microcapsule which is distinct from that resulting from a first activity.
59. A method according to claim 58, wherein the change resulting from the second activity is used to positively select the microbeads or microcapsules.

60. A method according to claim 58, wherein the change resulting from the second activity is used to negatively select the microbeads or microcapsules.

61. A method according to claim 60, wherein negative selection is combined with positive selection to improve reaction specificity.

62. A method according to claim 61, wherein the improved reaction specificity is an improvement in binding specificity.

63. A method according to claim 61, wherein the improved reaction specificity is an improvement in regio- and/or stereo-selectivity for the target.

64. A method according to claim 24, wherein microbeads modified directly or indirectly by the activity of the compound are further modified by Tyramide Signal Amplification (TSA™; NEN), resulting directly or indirectly in a change in the optical properties of said microbeads thereby enabling their identification and, optionally, isolation.

65. Method according to claim 24, wherein the compound or compounds are low molecular weight compounds.

66. Method according to claim 24, wherein each microbead has attached thereto multiple molecules of a single compound.

67. A method according to claim 24, wherein microencapsulation is achieved by forming a water-in-oil emulsion.

68. A method according to claim 67, wherein the water-in-oil emulsion is made using a microfluidic system.

69. A method according to claim 68, wherein the emulsion is formed by aqueous droplet break off in a co-flowing steam of an immiscible liquid.
70. A method according to claim 68 or claim 69 wherein microcapsules are transported for analysis by laminar-flow of aqueous microdroplets dispersed in a stream of oil in microfluidic channels.

71. A method according to claim 70, wherein the microcapsules are of aqueous microdroplets dispersed in a stream of oil in microfluidic channels.

72. A method according to claim 71, wherein the compound in a microcapsule is identified by the relative position of the microcapsule compared to other microdroplets in a microfluidic channel.

73. A method according to claim 71, wherein the concentration of a compound in a microcapsule is identified by the relative position of the microcapsule compared to other microdroplets in a microfluidic channel.

74. A method according to claim 71, wherein the target in a microcapsule is identified by the relative position of the microcapsule compared to other microdroplets in a microfluidic channel.

75. A method according to claim 64, wherein the identified microcapsules are sorted using a microfluidic device.

76. A method according to claim 67, wherein microencapsulation is achieved by forming an emulsion with a fluorocarbon or perfluorocarbon continuous phase.

77. A method according to claim 76, wherein microencapsulation is achieved by forming an emulsion with a fluorocarbon or perfluorocarbon continuous phase and a non-aqueous discontinuous phase.

78. A method according to claim 76, wherein microencapsulation is achieved by forming an emulsion with a fluorocarbon or perfluorocarbon continuous phase and an aqueous discontinuous phase.

79. A method according to claim 76, wherein the fluorocarbon is perfluoroctyl bromide or perfluoroctylethane.
80. A method according to claim 78, wherein the emulsion is formed using F-alkyl dimorpholinophosphate(s).

81. A method according to claim 80, wherein the F-alkyl dimorpholinophosphates have the general formula \( C_nF_{2n+1}C_mH_{2m}OP(O)[N(CH_2CH_2)_2O]_2 \).

82. A method according to claim 81, wherein the F-alkyl dimorpholinophosphate is \( C_9F_7C_11H_{22}OP(O)[N(CH_2CH_2)_2O]_2 \).

83. A method according to claim 24, wherein the microcapsules are identified and, optionally, sorted by detection of a change in their fluorescence.

84. A method according to claim 83, wherein the change in fluorescence is due to fluorescence resonance energy transfer (FRET).

85. A method according to claim 7, wherein the microbead is nonmagnetic, magnetic or paramagnetic.

86. A method according to claim 24, wherein the microbeads are identified and, optionally, sorted by detection of a change in their fluorescence.

87. A method according to claim 86, wherein the identification of microbeads is by flow cytometry.

88. A method according to claim 87, wherein the sorting of microbeads is performed using a fluorescence activated cell sorter (FACS).

89. A method according to claim 88, wherein the change in fluorescence is due to fluorescence resonance energy transfer (FRET).

90. A method according to claim 1, wherein the internal environment of the microcapsules is modified by the addition of one or more reagents to the oil phase.

91. A method according to claim 7, wherein the primary compounds are coupled to beads with different optical properties.

92. A method according to claim 91, wherein the beads have different fluorescent properties.
93. A method according to claim 92, wherein the different optical properties of the beads are due to incorporation of different levels of two or more fluorochromes into the beads.

94. A method according to claim 93, wherein the different optical properties of the beads are due to incorporation of different numbers of quantum dots with different emission spectra.

95. A method according to claim 94, wherein the different optical properties of the beads are used to identify the compound bound to the beads.

96. A method according to claim 7, wherein the compounds on the isolated beads are identified by releasing the compounds from the beads and direct analysis.

97. A method according to claim 96, wherein the compounds on the isolated beads are identified by mass-spectroscopy.

98. A method according to claim 1, further comprising the step of isolating the secondary compound produced by reaction of the primary compounds.

99. A method according to claim 1, further comprising the step of manufacturing one or more secondary compounds.

100. A method according to claim 14, wherein a compound and a target are initially located in different microcapsules which are subsequently fused.

101. A method according to claim 1 wherein microcapsules containing different subsets of compounds are fused.

102. A method according to claim 1, wherein a microcapsule containing a compound is split to generate two or more microcapsules.

103. A method according to claim 14, wherein a microcapsule containing a target is split to generate two or more microcapsules.

104. A method according to claim 1, wherein a cell or cells are located in a microcapsule.
105. A method according to claim 1, wherein the compound modulates the activity of a target in the cell(s).

106. A method according to claim 1, wherein the compound modulates an activity of the cell(s).

107. A method according to claim 1, wherein one or both of steps (a) and (b) is performed under electronic microfluidic control.

108. A method according to claim 106, wherein the technique of electronic microfluidic control involves generating an electric charge in at least a proportion of the microcapsules.

109. A method according to claim 107, wherein the step of generating an electric charge in at least a proportion of the microcapsules comprises applying an electric field to at least a proportion of those microcapsules.

110. A method according to claim 107, wherein the electric field is generated within a microfluidic channel.

111. A method according to claim 109, wherein the electric field is at least 0.1V/microlitre.

112. A method according to claim 111, wherein the electric field is generated using at least one electrode within the microfluidic channel.

Further documents are listed in the continuation box C. Patent family members are listed in annex.

* Special categories of cited documents:

*A* document defining the general state of the art which is not considered to be of particular relevance

*E* earlier document but published on or after the international filing date

*L* document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)

*O* document referring to an oral disclosure, use, exhibition or other means

*P* document published prior to the international filing date but later than the priority date claimed

*P* later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

*X* document of particular relevance; the claimed invention cannot be considered as novel or cannot be considered to involve an inventive step when the document is taken alone

*Y* document of particular relevance; the claimed invention cannot be considered as involving an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art

*Z* document of the same inventor

Date of the actual completion of the international search

14 December 2005

Date of mailing of the international search report
